## Flight Simulator II Scenery Disks

## The Challenge of Accomplished Flight

With a realism comparable to (and in some ways even surpassing) $\$ 100,000$ aircraft flight simulators, Flight Simulator II includes full flight instrumentation and avionics, and provides a full-color out-thewindow view. Instruments are arranged in the format standard to modern aircraft. All the radios needed for IFR flight are included. Front, rear, left, right, and diagonal views let you look in any direction. Program features are clearly documented in a 96 -page Pilot's Operating Handbook.

For training in proper flight techniques, Flight Simulator II includes another 96 -page instruction manual, compiled by two professional flight instructors with over 8,000 hours flight time and 12,000 hours of aviation teaching experience. You'll learn correct FAA-
recommended flight procedures, from basic aircraft control through instrument approaches. To reward your accomplishments, the manual even includes a section on aerobatic maneuvers.

## The Realism and Beauty of Flight

Go sight-seeing over detailed, realistic United States scenery. High-speed graphic drivers provide an animated out-the-window view in either day, dusk, or night flying modes.

Flight Simulator II features over 80 airports in four different scenery areas: New York. Chicago, Seattle, and Los Angeles. Six additional Scenery Disks covering the entire Western half of the United States are now available in IBM and C64/I28 disk formats.

Apple II is a trademark of Apple Computer. Ine. Atari XL and XE are trademarks of Atari Corp.

Apple and Atari versions will be released soon. Each disk covers a geographical region of the country in detail, and is very reasonably priced.

## The Pure Fun of "World War I Ace"

When you think you're ready, you can test your flying skills with the "World War I Ace" aerial battle game. This game sends you on a bombing run over heavily-defended enemy territory. Six enemy fighters will attempt to engage you in combat as soon as war is declared. Your aircraft can carry five bombs, and your machine guns are loaded with 100 rounds of ammunition.

See Your Dealer. Flight Simulator II is available on disk for the Apple II, Atari XL/XE, and Commodore 64/I28 computers for $\$ 49.95$. Scenery Disks for the C64 and IBM PC (Jet or Microsoft Flight Simulator) are $\$ 19.95$ each. A complete Western U.S. Scenery six-disk set is also available for $\$ 99.95$. For additional product or ordering information, call (800) 637-4983.

# We don't care which computer you own. Well help you get the most out of it. 

CompuServe puts a world of information, communications, and entertainment at your fingertips.

CompuServe is the world's largest information service designed for the personal computer user and managed by the communications professionals who provide business information services to over one quarter of the FORTUNE 500 companies.

Subscribers get a wealth of useful, profitable or just plain interesting information like national news wires, home
shopping and banking, travel and sophisticated financial data. Plus electronic mail, national bulletin boards, forums (special interest groups), and a multichannel CB simulator.
You get games and entertainment, too. Board, parlor, sports, space and educational games. Trivia and the first online TV-style game show played for real prizes.

## BLOCK BUSTERS.

Ever run into a mental block while doing your homework? Like how to start an essay? Or solve a tough math problem?

Well now there's help. The HOMEWORK HELPERS'w from Spinnaker. They're designed to bust these blocks and help you produce your homework assignments.

Through a unique system of prompts, the HOMEWORK HELPERS ask stimulating questions, inspire new ideas, and help you organize. And they cover two of the toughest homework challenges: writing well and solving math word problems.

Take WRITING. It has a unique, 3-part program for developing essays and book reports. It gets you started by asking key questions and shows how to organize an
outline. Then its built-in word processor actually helps you write, edit, and print out the final work.

Then there's MATH WORD PROBLEMS. Its special grid system helps translate word problems into workable equations. It has a built-in calculator which shows the solution step-by-step and prints out homework calculations ready to hand in.

The Spinnaker HOMEWORK HELPERS are the mental block busters that produce homework results. Look for them at your local software retailer.

## $\square$ BOOKREPORT CREATEIDEAS

What is the theme - the main idea - of Great Expectations? Type your answer.

Finding the theme sometimes takes a little digging Press Ctrll $H$ for some common themes.
Some common themes are: the power of love, the triumph of persistence, the beauty of nature, greed, intolerance, alienation, escape from conformity, the journey of life.

We make learning fun.

# How to turn your computeron. 

(The following is an actual conversation between Bantam Software and an unusually talkative personal computer).
BANTAM SOFTWARE: We always ask what turns people on. Now we want to know what turns you on. PERSONAL COMPUTER: It's about time someone asked the real expert. What turns me off is boring software. Boring, uninvolving, predictable software. And cold rooms. Why is it always so cold in here?
B: Games and Ahoy magazines called Sherlock Holmes in "Another Bow" one of the year's best.
PC: Let me decide. Okay? (Disk inserted.) Well, this is anything but elementary. You're Holmes. Watson's at your side. And you determine your own fate in case after case. And look, you run into the likes of Picasso, Gertrude Hen ry Ford, Louis Armstrong. Ana - such graphics! These derive from early 20th century photographs. I don't have a clue how you did it, but you have a winner. Next case.
B: The Fourth Protocol, from Frederick

nuclearweapons. A British traitor. The KGB. And the subversion of NATO. This is a challenge.Will it help if I read the book? (Loud explosion on screen.) Oh no! Does that mean I lost? B: No, but losing's the whole point of the next one. The Complete Scarsdale Medical Diet. You know the bestseller. PC: Why, do I look heavy? Never mind, let's have a taste. (Disk is inserted.) This is some menu. It helps you assess your goals. Monitor your progress. Mix'n match meals from all five Scarsdale diets. Even prepares your shopping list. It'll tell you how much exercise you need to work off certain foods. Let's see about kiwi tart...
B: We've got one other program.
PC: No more. I'm exhausted.
B: No...this is a rebate program. Just fill out the coupon and mail it with proof of purchase and you get $\$ 5.00$ back. PC:Thank you. That's a nice offer. $\mathrm{B}:$ So, did we turn you on?

PC: Yup. Now, please turn me off so I can rest. I've got to do some running later on to work off that kiwi tart.

Sherlock Holmes available for: Apple // Series, Commodore 64/128 IBM PC/PCjr, Macintosh.

## Editor's Notes

Now that the hubbub is dying down after the introduction of Atari's ST and Commodore's Amiga, those longawaited, powerhouse, new-generation computers, perhaps it's a good time to reflect on their relative merits. Although not much software is yet available to show them off to best advantage-a few adventure games, utilities, and applications programs so far-some conclusions can already be drawn.

We've been writing and editing Amiga and ST books and articles here for some months, and our staff is already segregating into camps. We've had camps, of course, for years: Apple enthusiasts, Commodore fans, Atari aficionados, IBM devotees, and assorted other, smaller, clusters of allegiance. It all makes for some spirited exchanges on the relative merits of the competing technologies and, we like to think, energizes our writing and programming.

For example, one of the major responsibilities of our programming staff is transporting programs between machines. We'll transport an arcade game with excellent graphics from its original home to several new computers with varying screen, color, sprite, character, and sound capabilities. This sort of thing throws the differences between computers into high relief.

The Amiga and the ST are quite similar in many respects: Each has a 68000 chip; 512 K RAM (although the Amiga is advertised as having only 256 K RAM, since the rest is reserved for storing the disk-based operating system); $3^{11 / 2}$-inch disk drive; mouse; windows; pull-down menus; RS-232 port; parallel printer port; and high-resolution color graphics.

The most striking difference, perhaps, is the price: with color monitor and disk drive, the Amiga costs $\$ 1,800$, $\$ 800$ more than the ST. For this extra money, you get multiprocessing, which allows you to run more than one program at a time. The Amiga also offers a more complex sound system with four voices in stereo to the ST's three in mono. The Amiga has $640 \times 400$ and $640 \times 200$ resolution modes with 16 simultaneous colors, a $320 \times 200$ mode with 32 colors, and a total palette of 4,096 colors. The ST has a $640 \times 400$
monochrome mode, a $640 \times 200$ mode with 4 simultaneous colors, a $320 \times$ 200 mode with 16 colors, and a total of 512 colors.

Thus, some of the specs would favor the Amiga if, for example, you need extraordinary degrees of color or resolution. Some argue that differences between color number 3,067 and 3,068 are extremely difficult to detect and that this palette represents overkill; others disagree. The Amiga has specialized chips dedicated to memory moves, fills, and other graphics and sound techniques. This frees up the 68000 to do other things while graphics are being manipulated (an important consideration on a computer with a bitmapped, graphics-oriented display). On the other hand, the ST allows the 68000 to run somewhat faster than does the Amiga.

An ST disk holds 360 K , the Amiga 880 K (although double-sided ST drives with 720 K are an option). The Amiga has built-in speech synthesis, but the ST has a built-in MIDI interface for controlling external synthesizers and drum machines. The ST has a built-in hard disk interface; the Amiga requires an additional interface.

Many of the differences between the machines can be eliminated, however, by upgrading, adding peripherals, cards, or options. For example, Commodore will offer a plug-in MIDI interface, and, doubtless, speech synthesis will be made available for the ST. Commodore has announced and demonstrated IBM compatibility via a software emulator, opening up a huge software base. Of course, ST developers are likely to be working on this, too.

While not claiming that the COMPUTE! staff represents a microcosm of the computer marketplace, we have heard effective defenses of both computers. One of our ST partisans says that the disk I/O is faster; software is in greater supply; the operating system and hardware have been around longer and are therefore more fully tested; the machine is easier to understand; there's more speed except for graphics-oriented computing; the keyboard is excellent; the debugger is better; nobody needs multitasking (who could stay in control while simultaneously supervising a spreadsheet and calling a bulletin
board?); anything you want that the ST doesn't have you can add; and so forth.

An Amiga owner insists that his computer can expect a great deal of software very soon (the ST was released earlier, and much of its current software comes from Europe where the Amiga has yet to be introduced); the Amiga is hardly an untested technol-ogy-it's been in development for three years; the difference in the clock speeds is rendered irrelevant because of the layers of systems, software, languages, and applications above a clock; such things as area fill are built into the Amiga hardware which further counters any clock differences; adding on things not built into the machine results in a pile of extra cords and extra expense; built-in speech means that all programs can use that feature without worrying about compatibility; multitasking is quite useful-having more than one program resident in RAM avoids disk-swapping or rebooting and also allows unrelated software to act as if it were an integrated package.

Rising to the occasion, the ST proponent counters that provisions for multitasking are possible in the ST as well. And so it goes.

At user groups, in magazines, and on telecommunications services around the country, advocates urge one another to get realistic and accept the fact that machine A is obviously better than B . Any comparison of them is contrapuntal; any argument designed to demonstrate the superiority of one can be met by an equally convincing counterargument. It's not surprising that this debate has vitality. After all, the COMPUTE! staff has been working closely with many different machines for years and, with rare exceptions, our Atari camp has never been able to convert the Commodore camp and vice versa, not to mention the solidity of Apple, IBM, and other allegiances. It appears that the ST and Amiga have raised new flags and are likely to perpetuate the friendly faceoff that's been an energizing force in personal computing for a decade.

Senior Editor

## THE SHADOW

$\$ 89.95$
Shadow is a new and revolutionary piece of hardware that is used to duplicate even the most protected software. Fitting inside the disk drive (no soldering required), SHADOW takes complete control of all functions giving near $100 \%$ copies.

Being the best utility available today, it will even copy the other copy programs.

Because of the Shadow's unique abilities, we feel DOS protection is a thing of the past.

MegaSort

## *HACKER PACKAGE $\$ 39.95$

Shadow a disk while it loads, then read an exact list of:

- Track, sector, ID, check sum, drive status
- High and low track limits
- Density use on each track
- Half tracks that are used
- Command recorder shows commands that were sent to 1541 while program was loading
- RAM recorder records custom DOS

Shadow-scan any disk, then read exact list of:

- Valid tracks, half tracks, partial tracks and segments
- Sync mark link, header block links and data block links
- Track to track synchronization

Exclusive snap shot recorder will give you an exact copy of the 1541 RAM and can be viewed, saved or printed. Plus many more features included.
*Requires Shadow
P.O. Box 1080 - Battle Ground, Washington 98604 1.800-541-1541

Canadian/Foreign Orders Call (206) 687 -5205
*GT PACKAGE
$\$ 44.95$
Highly sophisticated and integrated piece of hardware that turns you 1541 into something you've always wanted.

- Track and sector display
- Drive reset switch
- Device number change
- Half track indicator
- Abnormal bit density indicator
- Shadow on-off indicator

The Shadow display will give you an accurate display of precisely what track you are accessing during a normal load even if the program does a read past track 35 . -Requires Shadow

Order by phone 24 hrs. 17 days or send cashier's check/money order payable to Megasoft. Visa, MasterCard include card number and expiration date. Add $\$ 3.50$ shipping/handling for continental U.S., $\$ 5.50$ for UPS air. CODs add $\$ 7.50$, Canada add $\$ 10.00$. Other foreign orders add \$15.00 and remit certified U.S. funds only. Distributors invited and supported.

MacTalk: Telecomputing on the Macintosh
Sheldon Leemon
Arlan Levitan
A complete guide to telecomputing on the Macintosh from choosing a modem and software to accessing information services and electronic bulletin boards.
\$14.95 ISBN 0-942386-85-X

COMPUTE!'s Telecomputing on the IBM
Arlan R. Levitan
Sheldon Leemon
The ins and outs of telecomputing on the IBM PC or PCjr, selecting a modem and evaluating terminal software, how to go online with the major information services.
\$14.95 ISBN 0-942386-96-5

## COMPUTE!'s Telecomputing

 on the Commodore 64 EditedIntroduces readers to telecommunications, with sections on buying and using modems, accessing information services and bulletin boards, and uploading and downloading files. There is also a disk available which includes the programs in the book.
\$12.95 ISBN 0-87455-009-2

Telecomputing lets you call up computers around the world through a network of telephone lines.
To get you started in telecomputing, COMPUTE! Books offers you five top-selling books. Written for the Apple II-series, Commodore 64, IBM PC and PCjr, and Macintosh, the books give you all the information you need, from selecting software to dialing large databases.
To order your complete guide to telecomputing, give us a call. In the U.S., call toll free 1-800-346-6767 (in NY call 212-887-8525).

## COMPUTE!'s Personal Telecomputing

Don Stoner
This comprehensive general guide to the world of telecomputing shows how to access databases, receive software, and communicate with others using a personal computer.

## COMPUTE!'s Guide to

Telecomputing on the Apple
Thomas E. Enright
Joan Nickerson
Anne Wayman
An informative, easy-to-understand guide to telecomputing on the Apple: covers everything from selecting hardware and software to accessing large databases.
\$9.95 ISBN 0-942386-98-1

#### Abstract

If you have any questions, comments, or suggestions you would like to see addressed in this column, write to "Readers' Feedback," COMPUTE, P.O. Box 5406, Greensboro, NC 27403. Due to the volume of mail we receive, we regret that we cannot provide personal answers to technical questions.

## A Few Helpful REMarks

I suppose this isn't a new idea, but whenever I type in a program printed in COMPUTE!, I add one or two REM lines near the beginning to indicate the program's name, the date, and the page number where it appeared. That way, if I forget some command and can't get the program to work correctly, I can always find the COMPUTE! article which accompanied that program and reread the instructions.

John Hibbs
After a few weeks or months have elapsed, it's easy to forget exactly how a program works, even if it's one you wrote yourself. In most cases, you can't harm a program by adding a couple of REMs. However, you should be careful not to disturb existing lines unless you know exactly what the program is doing. Also, this technique is limited to BASIC programs. Some machine language programs such as Commodore 64 SpeedScript begin with a line of BASIC (usually something like 0 SYS2061) so that you can load and run the program as if it were BASIC. If you try to add a REM to such a program, it probably won't work at all.

## Computers For Charity

I represent a charitable, nonprofit organization that uses microcomputer equipment in virtually every aspect of its affairs. We would be grateful if your readers would consider contributing additional equipment. Donations of this sort can have substantial financial benefits. If you are in a position to contribute or would like more information, please contact me at the following address or call (617) 495-9020. Collect calls will be accepted.

[^0]Virtually every locale has a variety of organizations which may benefit from contributions of computer equipment. Donations may also be tax-deductible. Any readers who want to find out what's available in their area can contact the nearest chapter of the United Way for information about local charitable and volunteer organizations.

## Digitized Amiga Sound

In the September 1985 issue of COMPUTEI, you mentioned that the Amiga computer will be able to digitize music. If I were to plug the output from a stereo system or a radio into the Amiga, could it record the music and play it back exactly like the original? How many different voices does the Amiga computer have?

Robert Patterson
The answer to your first question is a qualified yes. The Amiga can play back digitized sound, but you can't plug your stereo output directly into an Amiga and expect to record music without additional hardware and a program to control it. The output from conventional sound equipment is an analog signal, whereas the Amiga, like other computers, deals only with digital information (binary 1's and 0's). Before doing anything else, you'll need to pass the analog signal through an analog-to-digital ( $A$-to-D) converter to put it in a form the computer can use. That sounds more forbidding than it really is: The components for $A$-to-D converters are cheap and readily available, and it probably won't be long before you see reasonably priced plug-in digitizers for the Amiga.

Assuming you can convert the incoming signal to digital form, the computer must then sample the signal at a rapid rate-usually thousands of times per second. At each sampling interval, it stores a numeric value which represents the sound input at that point in time. The more frequently you sample the sound, the higher the quality of reproduction-and the more memory is required. The Amiga's 68000 microprocessor runs fast enough to sample incoming signals at an extremely high rate-rivaling the quality of compact disc sound-but even 512K of RAM isn't enough to record significant amounts of high-quality music. Remember that a
compact disc can store only $u p$ to 75 minutes of music with its capacity of 550 megabytes $(563,200 \mathrm{~K})$. At that sampling rate, a 512 K Amiga could barely record four seconds of music. Of course, by lowering the sampling rate (and accepting somewhat lower quality), that duration can be extended.

At the end of the digital sampling process, the computer has thousands of sample values stored in memory, which can be saved to disk for future use or output directly through a sound channel. To output the digitized sound, you simply reverse the process, reading the stored data from memory, converting it from digital to analog form, and sending the resulting signal to a conventional amplifier at the same rate it was sampled. The Amiga already contains circuitry that can perform the D-to-A conversion at the output end of the process, so sending digitized sound out doesn't require any extra hardware at all.

To answer your second question, the Amiga has four independently programmable sound channels (voices). However, it's difficult to compare them to sound channels on other computers because they're considerably more flexible than tone generators. Most computers are limited to producing one or several basic waveforms, but the Amiga lets you define your own waveforms. And since one channel can modulate (affect) another, it's possible to create extremely sophisticated sounds. Any single channel can simulate a complex waveform, so individual channels can make sounds which would require several channels on other computers. Two of the four channels are assigned to each of the Amiga's stereo outputs, so realistic stereo effects are fairly easy to achieve. The Amiga version of "Switchbox," found elsewhere in this issue, creates stereo effects by switching sounds back and forth between the two stereo outputs.

## Moving The New Proofreader's Checksum

When I use the "Automatic Proofreader" with my Commodore 64, the checksum is displayed too high on my screen to be visible. Is there any way to modify the program so it prints the checksum lower on the screen?

Melvin Baral

# $\operatorname{sen} x$ <br> pers: <br> wrisjucins Riseleoviranill 

You've joined an elite Rescue Squadron, flying to the hostile planet Fractalus to confront the ruthless enemy Jaggies head on. The mission is a treacherous one for, as everyone knows, the cyanitric acid atmosphere on Fractalus is fatal and Jaggi saucers are cunning. You're needed to rescue Ethercorps pilots shot down and stranded on that brutal planet, and to help lead our forces to victory for the merciless Jaggi onslaught must be stopped to preserve the future of our galaxy.

Rescue on Fractalus! is a rescue and space action game with realistic 3-D flight simulation. You pilot your Valkyrie Fighter through the canyons and around the mountain peaks of the planet Fractalus to rescue fellow
pilots, do battle with enemy saucers and destroy enemy gun emplacements.
We supply the Long Range Scanner, Dirac Mirror Shield and Anti-Matter Bubble Torpedoes . . . YOU supply the skill and guts! Take the challenge: The perils of Fractalus await you.

1043 Kiel Ct., Sunnyvale, CA 94089

See specially marked boxes for details. No purciase necessary. Sweepstakes ends Dec. 31, 1985. Official rules available at participating dealers

[^1]The problem you mention is typical of TV sets or monitors that suffer from severe overscan (they can't display all of the picture on the screen). If you can't adjust the picture to include the top screen line, you'll have to modify the program. In this issue, we're introducing the "New Automatic Proofreader" for Commodore computers, which works on the 64, 128, VIC20, Plus/4, and 16. Though it's designed to print the checksum in the upper-left corner of the screen, the new Proofreader can be made to print it elsewhere. First, follow the instructions in the article for typing and saving the new Proofreader. Then reload it and make the following changes:

- In line 80, change 20570 to 20551.
- In line 110, change 22054 to 22035.
- In line 190, change 19 to 0.

Now resave the program, using a different filename so you can tell it apart from the original version. The modified Proofreader prints the checksum just below the last line entered, rather than at the top of the screen. You can either type the next line number over the checksum, or move the cursor down to the next blank line and then start typing. Since this modification makes the Proofreader less convenient for listing and rechecking a group of existing program lines, you probably won't want to make this change unless it's absolutely necessary.

## Checking Apple DOS From BASIC

How can an Apple II BASIC program check to see which operating system is running?
P. Nyman

There are quite a few differences between DOS 3.3 and ProDOS, but with a little care, a BASIC program can run under either operating system. You can tell which system is active by PEEKing memory location 48640 . This is the start of the BASIC System Global Page in ProDOS, and contains operating system variables which a BASIC programmer might want to read or change. Since the page begins with a machine language JMP (jump) instruction, this first byte has a value of 76 under ProDOS. When you use DOS 3.3, the same byte contains 208. Here's a simple routine that does what you want:
10 IF PEEK ( 48640 ) $=76$ THEN PRINT
"PRODOS INSTALLED":GOTO 30 20 PRINT "DOS 3.3 INSTALLED" 30 REM PROGRAM CONTINUES HERE

## Atari Compiler Problem

I own an Atari 800XL and frequently use Datasoft's BASIC Compiler to compile my own BASIC programs. I recently tried to compile a public domain terminal program called "Amodem 7.1," with unsatisfactory results. The
compiler won't accept statements that GOTO or GOSUB a variable or expression. The author of the terminal program used the common memory-saving technique of defining often-used numbers as variables ( $\mathrm{C} 1=1$, and so on). I have converted the variables back to numbers, but the GOTO and GOSUB statements still refer to expressions (for instance, GOTO 3*100 instead of GOTO C3*C100). Can you write a routine that will take me the rest of way, or lead me on the right track?

Dennis Brenner
Since we don't have the terminal program in question, we can't give a specific answer. However, it's not very practical to write a routine that will solve your problem automatically. You'll need to analyze each of the problem statements to determine whether it always branches to the same destination, or branches to different destinations depending on the controlling variable's value. To explain, say that you find the statement GOTO C3*C100 and discover that $C 3=3$ and $C 100=100$. If it's clear that the values of C3 and C100 never change, you can replace the statement with GOTO 300. However, the primary reason for using a variable expression with GOTO or GOSUB is to permit the program to branch to a variety of destinations depending on the variable's value.

For example, say that you find the same statement (GOTO C3*C100) and discover that C3 may have the values 1, 2, or 3 when this statement executes. Program flow will branch to line 100,200 , or 300 , depending on the value of C3. In this case, you can't replace the expression with a constant, since that would limit the branch to only one destination. The best alternative is to substitute ON-GOTO and ON-GOSUB. For instance, the statement ON C3 GOTO 100, 200, 300 branches to line 100 when $C 3=1$, line 200 when $C 3=2$, and so on. To make this work, you must determine all the possible values that the controlling variable (C3 in this case) might have, and compute all the destinations that might be generated by that expression. Once that's done, you'll know which line numbers to put at the end of the ON-GOTO or ON-GOSUB statement.

Most BASIC compilers accept only a subset of all the commands in BASIC, so it's possible that yours might not handle ON-GOTO or ON-GOSUB, either. If that's the case, you could replace the original statement with a string of IF-THENGOTO statements (IF C3 $=1$ THEN GOTO 100, IF C3 = 2 THEN GOTO 200, etc.). This construction is less efficient, but should work with almost any compiler. Tradeoffs of this sort are inevitable when compiling programs that weren't designed to be compiled.

## Saving IBM PC Screens

I'm writing a BASICA painting program for the IBM PC that does all the drawing with PUT commands. But I need to know how to save a picture to disk so my work isn't lost when I turn the computer off. I know you can store an entire screen in an array with a GET command like this:
10 DIM V(4001)
20 GET $(0,0)-(639,199), V$
How can I save the contents of this array to disk?

## David Short

It's a simple operation in BASICA. The VARPTR function can tell you the memory location where any array is stored, and BSAVE can save the contents of any block of memory, including arrays or other variables. Since each element of the array occupies four bytes, you must save 16004 (4*4001) bytes of memory. Use $\operatorname{VARPTR}(V(0))$ to find the location of the first element in the array. This statement saves the array $V$ in a file called PICTURE:
30 BSAVE "PICTURE",VARPTR(V(0)) ,16004

Here's a complementary program to load the same picture from disk and display it on the screen. Don't forget to DIMension the array before performing this operation.

## 10 DIM V(4001)

20 BLOAD "PICTURE",VARPTR(V(0)) 30 PUT (0,0),V,PSET

## Embedded BASIC Words

I usually pay little or no attention to spacing when typing BASIC programs, but when using "MLX II" to type in a program from the December 1985 issue of COMPUTE!, I ran into a puzzling problem. Everything worked fine until I tried to load data and received the message SYNTAX ERROR IN LINE 830. I rechecked the line and found that everything was correct, except that I hadn't used the same spacing shown in the magazine listing. When I corrected the spacing, the program worked perfectly. After a little further investigation, I discovered that the space causing the problem was between ST and AND. Why does that space make such a difference?

Jim David
Here's what that portion of line 830 looks like:

## IF ST AND (I $<>$ B)THEN $F=2$

Both AND and ST are reserved words in Commodore BASIC, meaning that BASIC lets you use them for only one purpose. ST (STatus) is a reserved variable that indicates the status of input/output operations like loading or saving to disk. AND

## COMPUTE!'s 128 Programmer's Guide <br> ISBN 0-87455-031-9 <br> Editors of COMPUTE! 464 pages

Written and compiled by the most technically proficient authors in consumer computing today, the technical staff of COMPUTE! Publications, this guide to the powerful Commodore 128 computer contains a wealth of information for every programmer. Explore BASIC 7.0 through countless hands-on examples and sample programs. Learn how to create dazzling graphics and sophisticated sounds in both BASIC and machine language. See how to program peripherals, such as disk drives, printers, and modems. Enter the world of $C P / M$, just one of the three modes of the 128. There are even chapters introducing you to machine language programming and the computer's method of managing memory. COMPUTEI's 128 Programmer's Guide includes numerous appendices covering everything from error messages to memory maps.
\$16.95

> Look for these new books at a bookstore or a computer store near you. Or order directly from COMPUTE! Books. Call toll-free 1-800-346-6767. In NY call 212-887-8525.

> Everything you need for successful, entertaining, and challenging programming on your Amiga, Atari ST, or Commodore 128 computer.

Each book is carefully written in COMPUTE!'s lively, understandable style to help even beginning programmers learn the ins and outs of their personal computers.

## COMPUTEI's ST Programmer's Guide 0-87455-023-8

Editors of COMPUTE!
Complete and comprehensive, yet easy to understand, COMPUTEI's ST Programmer's Guide is a must-buy for any Atari ST owner. The technical staff of COMPUTE! Publications has put together a reference guide to programming that takes the reader through every aspect of this newest Atari personal computer. Logo and BASIC, the two programming languages now available for the machine, are explored in detail. From programming concepts to writing programs, the scores of ready-to-type-in examples show just what can be done, and how to do it. Advanced features of this new-generation computer, such as GEM and TOS, the ST's user interface and operating system, are illustrated as readers write their own applications. Valuable appendices provide information programmers need, including GEM VDI opcodes and a list of ST resources.

## COMPUTE!'s Amiga Programmer's Guide 0-87455-028-9 <br> Edited

Covering AmigaDOS, BASIC, Intuition, and the other important programming tools which accompany the new Amiga, COMPUTE!'s Amiga Programmer's Guide is a clear and thorough guide to the inner workings of this fascinating, new-generation computer. The great speed of its 68000 microprocessor, coupled with the versatility of the Amiga-specific graphics and sound chips, makes the Amiga one of the most powerful computers available today. Written by the technical staff of COMPUTE! Publications, the most technically knowledgeable authors in computing today, this book is your key to accessing the Amiga's speed and power.
$\$ 16.95$ (March Release)

COMPUTE! books are available in the U.K., Europe, the Middle East, and Africa from Holt Saunders, Ltd., 1 St. Anne's Road, Eastbourne, East Sussex BN21 3UN, England.
is a logical operator which in this case connects the value of ST with the value of the expression $(I<>B)$.

Typing STAND $(I<>B)$ instead of ST AND $(I<>B)$ makes the computer see a third reserved word in the line-the numeric function TAN (TANgent). Since TAN, like other functions, must be followed by something inside parentheses, the computer responds with a syntax error message when it finds the letter $D$ instead of a left parenthesis. That's a nutshell explanation for the error. But you may still wonder why the computer sees TAN inside the word STAND. After all, the words ST and AND seem to be there as well.

The short program below shows exactly why TAN appears. Don't worry about the fact that line 10 looks strange. We're not going to execute that line-it's only there to let us examine how BASIC handles these reserved words.

## 10 :ST:TAN:AND::STAND::

20 PRINT CHR\$(14);CHR\$(147)
30 FOR J=0 TO 19:POKE 1024+J,
PEEK (2049 + J):POKE $55296+\mathrm{J}, 1:$ NEXT
After typing the program, enter GOTO 20 and press RETURN (don't start the program with RUN). Line 30 PEEKs the first 20 bytes of BASIC program space and displays their contents on the screen, showing you how the computer stores line 10 in memory. As you'll see, the reserved variable ST is stored as the ASCII characters $S$ and $T$, exactly what you typed in. This is the way all variable names are stored. However, both TAN and AND are changed into one-byte tokens, which appear here as reverse video characters. Most BASIC words are tokenized-compressed into a single numeric value-to save space and make BASIC run faster. Between the double colons we placed in the line as markers, you can see how the computer handles the character sequence S-T-A-N-D. When it tokenizes a BASIC line, the computer reads from left to right, just as you do. The initial S in STAND is left unchanged, since it isn't part of a keyword that can be tokenized. Next, the computer finds the characters $T-A-N$, which it replaces with the one-character token for TAN. That leaves the character $D$, which is also left unchanged.

After TAN is tokenized, the computer can't possibly see ST or AND (T and AN are missing), so the line can't work as intended. In this case, it was coincidental that the combination of two reserved words made a third reserved word. However, the same thing would happen if you omitted a space between ST and the logical operator OR. When the computer scans the characters S-T-O-R, it changes the embedded keyword TO into a token. For similar reasons you should be careful not to use variable names like TOP, NOTE, or FORK, which also contain embedded BASIC words (TO, NOT, and FOR).

## Arabian Atari Revisited

In the December 1985 "Readers' Feedback" you printed a letter from Nour Abdullah Al-Rasheed asking how to make the cursor on his Atari computer move from right to left. He may want to consider a hardware solution. The images displayed by a television set or monitor are placed on the screen by vertical and horizontal deflection circuits. An experienced electronics technician who's familiar with video displays should be able to examine the schematic for that device and determine which wires control horizontal deflection. By rewiring that circuit, the technician could bring about the desired change. This modification should probably be considered permanent; and it may require some adjustment of normally untouched internal controls to get a satisfactory picture. While it might be possible to install a switch that would let you flip back and forth between display modes, the technician would have to use special insulating spacers and take pains to protect the operator from the very high voltages involved.

> Jim Taylor

Thanks to you and the other readers who suggested this solution. As you point out, the circuitry involved carries extremely high voltages that can cause very serious injury, so this type of modification must be performed by a fully qualified technician. Unless you fit that category, don't even consider poking around inside your TV or monitor. You may cancel any warranty which is in effect, and run a serious risk of injuring yourself as well as the device.

## Refurbishing Tip

I really appreciate the article "Refurbish Your 64" from the December issue of computel. Here is an additional convenience feature. If you change line 3470 to read as follows, you won't have to enter the direct mode statements (POKE 55,0:POKE 56,160:POKE 643,160:POKE 644,160:NEW) after the program is run.

## 3470 READ A0:IF A0 $=99999$ THEN POKE253,253:SYS49194:POKE643,0 :POKE644,160:NEW

Albert Alarie
Thanks for the tip.

## TI Music

I have seen TI-99/4A programs that create music with DATA statements. Please show me how this is done.

Tim Huemmer
Though the DATA statements play a part in the process, the TI actually makes
sound with CALL SOUND. Here's the simplest form of the statement:

## CALL SOUND $(d, f, v)$

The first value in parentheses (d) sets the duration for the sound. The second value (f) sets the frequency, and the third $(v)$ sets the volume. CALL SOUND lets you produce as many as four tones at once, so with a statement like CALL SOUND ( $d, f 1, v 1, f 2, v 2, f 3, v 3$ ) it's possible to create a three-note chord. In this case, f1, f2, and $f 3$ represent the frequencies of the three notes, and v1, v2, and v3 represent their respective volumes. Of course, in a program you'd substitute real numbers or variables inside the parameters.

Where do DATA statements come into the picture? In most cases, it's simplest to read the music data from DATA statements and assign it to variables inside parentheses in CALL SOUND. This saves program space and makes the music data easier to understand and modify. Here's a short example of how it's done:
$100 \mathrm{~V}=5$
110 FOR I=1 TO 5
120 READ D,F1,F2,F3
130 CALL SOUND(D,F1,V,F2,V,F3,V)
140 NEXT I
150 DATA $1500,262,330,390$
160 DATA $250,262,349,440$
170 DATA $1500,262,349,415$
180 DATA $250,277,349,415$
190 DATA $1500,277,370,466$
200 DATA $250,262,392,466$
This program plays five three-note chords. Line 100 assigns the value 5 to the variable V. Since the CALL SOUND statement uses $V$ to set the volume for every note, it stays the same throughout the program. Line 120 READs in new DATA items for each chord, setting the duration with the variable $D$ and the three note frequencies with variables F1, F2, and F3. The frequency values for the notes are found in the appendix in the TI User's Reference Guide. You can read more about TI sound in COMPUTE!'s Programmer's Reference Guide to the TI99/4A by C. Regena. Several of her monthly columns in COMPUTE! have also covered this topic.

## Commodore B128 Users' Group

I was glad to see that Jim Butterfield's dynamic keyboard articles (COMPUTE!, October-December 1985) included some references to the Commodore B128 (called the B700 in Europe). As you may know, the international B128 user group is sending out 13,000 newsletter/membership applications to B128 owners in North America and B700 users in Europe. The group currently has 1,500 members, and membership is rapidly increasing. Our disk library is also off to a good start, and offers a variety of public domain

\section*{Booting PCJr In \(\mathbf{8 0}\) Columns}

I own an IBM PCjr, as do many of my coworkers. We would all like to know if there is any way to make the PCjr boot DOS 2.1 in an 80 -column format instead of 40 columns. Presently, to get DOS in 80 columns, I execute the program "Rebound" which was published in COMPUTE!. I then press Fn-Break, and the DOS prompt appears in 80 columns. Can you show me a simpler way?

\section*{Martin Gappa}

No tricks are needed to get 80 columns on the PCjr, since DOS has a command specifically for that purpose. Just type MODE 80 at the DOS prompt with the DOS disk in the drive. To get back to 40 columns, type MODE 40. Additional parameters let you shift the display left or right to center
it on the screen. MODE \(80, \mathrm{~L}\) shifts the display two characters to the left, and MODE 80,R shifts to the right. A third parameter, \(T\), displays a test pattern on the screen for precise alignment. For example, MODE 80,R,T shifts the display to the right and prints the digits 0-9 eight times across the screen. Then you're asked if you can see the leftmost 0 . If you can't, press \(N\) and the display shifts again followed by the same prompt. Press \(Y\) to return to the DOS prompt.

You can make the computer automatically switch to 80 columns when it's turned on by using a batch file. To create the batch file, insert one of your disks with system files on it and enter the command COPY CON AUTOEXEC.BAT. Then type MODE 80 and press the F6 function key (Fn-6) followed by Enter. When the drive stops spinning, display the directory: You should see the file AUTOEXEC.BAT. This file is automatically executed when you turn on the computer. For more information about batch files, see "All About IBM Batch Files" in the September and October 1985 issues of COMPUTE!. Since MODE is an external DOS command, you must also have the file MODE.COM on the same disk. To add this feature to all your boot disks, use the COPY command to copy both AUTOEXEC.BAT and MODE .COM to each disk.

8257 th Avenue． 0 th Floor．New York，NY 10019

Dramatic changes are occurring in the ways we store computer information. Technological advances and lower production costs are affecting both magnetic and optical data storage media. Traditional 51/4-inch floppy disks are giving way to \(31 / 2\)-inch microfloppies. Hard disk drives are rapidly becoming cost effective for average users. And lowpower lasers are making optical storage technology the medium of the future. Here's a look at how far and how fast data storage technology has come, and where it's headed next.

Just when we think we're getting used to the pace of change, technology surprises us again. Consider the following important changes to the ways we store computer data:
- Apple Computer introduces its UniDisk 3.5 , a \(31 / 2\)-inch disk drive for the Apple IIe and the Apple IIc computers that can store up to 800 K (kilobytes) of information, more than five times the amount of the standard Apple \(51 / 4\)-inch drives. - New \(31 / 2\)-inch drives are included as standard storage systems for Atari's 520ST and Commodore's Amiga, joining Apple's Macintosh which was introduced with the drive in 1984. Industry sources believe IBM will also begin using the faster, more powerful \(31 / 2\)-inch drives sometime in 1986.
- Blue Chip Electronics says it plans to offer a \(31 / 2\)-inch disk drive for the Commodore 64, tentatively priced at about \(\$ 100\). Commodore insiders admit that they already have the technology to offer a \(3^{1 / 2}\) inch drive and a 10 -megabyte hard
disk drive for the 64 and 128 (although no plans to market these peripherals have yet been announced). Atari also has been considering a \(31 / 2\)-inch disk drive for its line of eight-bit computers.
- Haba Systems is marketing a low-priced (\$699) 10-megabyte (10,240-kilobyte) hard disk drive for the Atari ST. Prices for 10- and 20-megabyte hard disks fall as low as \(\$ 400\) for some computers. Hard disks on a card are announced for the IBM PC.
- Toshiba, Hitachi, Philips, and several other companies announce CD-ROM (Compact Disc-Read Only Memory) players that can store entire encyclopedias or massive software libraries on just a portion of a \(43 / 4\)-inch optical laser disc.
- Maxell Corporation shows a new \(2^{1 / 2}\)-inch microfloppy disk drive that it plans to sell to manufacturers for use in laptop computers. The company also announces a 51/4-inch eraseable, reusable optical laser disc, which is to be marketed by 1987, and a new high-density perpendicular magnetic recording disk that packs up to 100 K of data per inch.

BASIC cross-reference Indispensible tool for BASIC programmers. Finds all references to variables, constants \& line numbers. Sorts in alphabetical order. C-64 \$17.95 C-128 \$17.95

\section*{ASSEMBLERMONTOR}

Macro assembler and extended monitor. Supports all standard functions plus floating point constants. Monitor supports bank switching, quick trace, single step, more.
\$39.95

\section*{Reference Books}

LDA \(^{\text {JSR }}\) DEC ROR IN INY TYA NOP TAX ROLSTA JMP INC PLA RTS CMPSTX SEC PLP SED

\section*{SUPERPASCAL}

Full Pascai supports graphics sprites, file management, more. Supports pointers, dynamic memory management, machine language. Compiles to fast 6510 machine code. C-64 \$59.95

C-128 \$59.95

\section*{SUPERCCOMPILER}

Full compiler, Kernighan \& Ritchie standard, but without bit fields. Includes powerful editor (41K source file); compiler, library (supports many functions) and linker. C-64 \$79.95 C-128 \$79.95

\section*{FORTH LANGUAGE}

Based on Forth 79 (+ parts of '83). Supports hires graphics and sound synthesizer. Full screen editor, programming tools, assembler, samples, handbook.
\$39.95

\section*{MASTER}

Professional development package for serious applications. Indexed file system, full screen \& printer management, programmer's aid, multiprecision math, royalty-free runtime, more.
\$39.95

\section*{VIDEO BASIC}

Add \(50+\) graphic, sound and utility commands to your programs with this super development package. Free distribution of RUNTIME version - no royalties!
\$39.95

\section*{ADA TRAINING COURSE}

Teaches you the language of the future. Comprehensive subset of language. Includes: editor; syntax checker, compiler; assembler; disassembler, handbook.
\(\$ 39.95\)
新

ANATOMY OF C-64 Insider's guide to the ' 64 internals. Graphics, sound, VO, kernal, memory maps, and much more. Complete commented ROM listings.

300pp \(\$ 19.95\)
ANATOMY OF 1541 DRHVE Best handbook on this drive, exptajpscaff. EHied with many examples programs ano puti) ities. Fully commented 1541 RQM) (istrings. \(500+p p \$ 19.95\)

MACHINE LANGUAGE FOR C-64 Learn 6510 code \& write fast programs. Many samples and listings for complete assembler, monitor and simulator.

200pp \$14.95
GRAPHICS BOOK FOR C-64 Best reference, covers basic and advanced graphics. Sprites, Hires, Multicolor, 3D-graphics, IRQ, CAD, projections, curves, more. \(350 \mathrm{pp} \$ 19.95\)

TRICKS \& TIPS FOR C. 64 Collection of easy-to-use techniques: advanced graphics, improved data input, enhanced BASIC, CP/M, data handling and more. \(\quad 275 \mathrm{pp}\) \$19.95

1541 REPAIR \& MAINTENANCE Handbook on the drive's hardware. Includes schematics \& techniques to keep 1541 running. Align drive w/ \& w/o scope. Large handbook size. \(\$ 19.95\)
ADVANCED MACHINE LANGUAGE Subects not covered elsewhere: video controller, interrupts, timers, VO, extensions to BASIC. Tips for the serious programmer. 210pp \(\$ 14.95\)

PRINTER BOOK C-64/VIC-20 Understand Commodore, Epson compatible printers \& 1520 plotter. Utilities, screen dump, 3D-plot, commented MPS-801 ROM listings. 330pp \(\$ 19.95\)

- Sony announces a writeable optical laser disc storage system for computer use in business, science, and major archival applications capable of storing up to 3.2 gigabytes \((3,276\) megabytes, or \(3,354,624\) bytes) per disc.

Virtually every week, another advance in data storage technology surfaces within the computer industry. What's going to happen to all of the \(51 / 4\)-inch floppy disks we're using now? Listen to Maxell's Ted Ozawa, vice president of the computer products division: "While we expect floppy disks to continue as a major industry factor for at least the next ten

Apple Computer's UniDisk 3.5 is a double-sided floppy disk drive that stores 800 K of data, one of a growing number of \(3^{1 / 2}\)-inch drives for popular microcomputers.
years, new technologies offering more portability or more storage capacity are being developed more quickly than previously anticipated."

Ozawa's comments are being echoed throughout the computer industry as breakthroughs in storage technology are coupled with swiftly falling prices. Even casual computer users are beginning to think in terms of megabytes-and, with CD-ROMs, gigabytes.

The computer industry is rapidly advancing in two related areas of technology. The most immediate and visible changes are the advances in magnetic technology, ushering in low-cost, high-capacity disks and drives for the mass market. At the same time, a second technology is gaining speed, less
visible but more important in the long run: laser discs designed for audio and video players are being tailored to computer data storage.

To understand the economies of scale involved with recent data storage improvements, consider that a typical \(5^{11 / 4}\)-inch doubledensity IBM floppy disk holds approximately 360 K of information. (By comparison, a Commodore 64 disk holds about 170K.) A doublesided \(31 / 2\)-inch disk contains approximately \(800-880 \mathrm{~K}\) of data. And an optical laser disc typically holds 550 megabytes, or the equivalent of almost 1,500 floppy disks (more than 3,500 Commodore 64 disks; more than 4,000 Apple II disks).

Such capacities are a far cry from the data storage devices used by many of the early microcomputer owners.A few years ago, modified audio cassette recorders were common storage devices on personal computers. They were inexpensive and usually reliable. Purchasers of Commodore VIC-20s, for example, and later Commodore 64 buyers, generally used Commodore Datassette recorders as a way to get started in computing for a fraction of the cost of a disk drive.

As with so much in the microcomputer field, magnetic tape storage was a descendant from mainframe computer systems. A cassette tape is a sequential access device. That is, tape moves sequentially across a recording head. In order to get to a program at the end of the tape, all of the preceding tape has to pass by the head first. The result is a frustratingly slow access time. More recent magnetic tape storage devices have used improved technology-data compaction, shorter loop tapes, and faster speeds-to remain competitive, at least as backup systems for hard disk drives.

With the advent of circular magnetic disks, also descendants of mainframe systems, many computer users decided to switch to the new medium. Although more expensive, random access storage offered significantly greater speed. A moveable read/write head could find information anywhere on the spinning disk almost instantaneously. The first floppy disks were either 8 inches (from IBM) or \(5 \frac{1}{1 / 4}\) inches (from Shugart) in diameter.

But the emerging micro industry quickly agreed on the smaller \(51 / 4\) inch disks that predominate today.

During the past three years, an even smaller-sized magnetic disk, the \(31 / 2\)-inch format, has gained popularity. With its faster access speeds, 800 K double-sided, double-density format, and sturdy plastic shell, the \(3^{1 / 2}\)-inch disk has definite advantages over the \(51 / 4\) inch standard. But when first introduced, so-called microfloppies came in at least three different sizes. Sony sold the \(31 / 2\)-inch disk, Dysan offered its \(31 / 4\)-inch style, and Hitachi announced a 3 -inch model. How did the \(31 / 2\)-inch disk become today's de facto standard?
"The thing that happened was that Sony was very aggressive in promoting its format, not only to media [disk] makers but to drive makers," says David Berry, product manager for Maxell, a division of Hitachi. First Hewlett Packard and then Apple Computer adopted Sony's \(31 / 2\)-inch format, which created a snowball effect toward the Sony size. Hitachi still markets its 3 -inch model, primarily in Japan

Maxell's new ultra-micro \(2^{1 ⁄ 2}\)-inch floppy disk holds 500 K of unformatted data and is planned for use in laptop computers and other selected markets.
and Europe, notes Berry. In fact, Maxell just introduced an even smaller, \(21 / 2\)-inch disk, that it hopes to sell in selected market niches. "But,". admits Berry, "we definitely think the \(31 / 2\)-inch will be the dominant force.

Regardless of their size, the physics of one floppy disk is similar to that of any other. An outer sleeve (vinyl for \(5^{1 / 4}\)-inch; hard plastic for \(31 / 2\)-inch) protects a circular disk that rotates on a disk drive's spin-

Looking similar to a standard \(31 / 2\)-inch microfloppy, Maxell's new perpendicular recording disk stands magnetic particles on end to pack up to 100 K of data per inch, about ten times the amount of a normal microfloppy.
ning hub at hundreds of revolutions per minute. There is a ferrousoxide coating on one or both sides of the disk. The drive's read/write head (or heads, if the drive is double-sided) can read and alter the arrangement of magnetic particles .Information is recorded on the disk in concentric rings, or tracks, that are divided into arc-shaped sectors. Drive and disk manufacturers are continually improving this technology to allow increasing amounts of data to be accessed at faster speeds. The newest floppy disks are capable of megabytes of storage, such as the IBM AT's 1.2megabyte floppy or Maxell's recently developed 10 -megabyte metal-formula floppy disk, which contains 41.7 K storage space per track and 120 tracks per side.

The next quantum leap in magnetic computer storage media is coming soon in the form of perpendicular recording technology. Magnetic floppy disks have heretofore used a standard metal oxide coating in which the particles lie horizontally on the disk surface. Perpendicular, or vertical, recording is analogous to the principle that more people can occupy a given space standing shoulder-to-shoulder than lying down side-by-side, explains Maxell's Ozawa.

Picture the magnetic particles "like a thickly clustered crowd of people standing in a field," he says.

Stripped-away views of two new \(31 / 2\)-inch Winchester-style 30 - and 20 -megabyte hard-disk drives from Peripheral Technology, Inc. Unlike floppies, these hard disks are nonremovable media.

Maxell has developed a perpendicular high-density disk that allows 100 K of data per inch, almost a tenfold storage increase over current recording densities. The company has worked with Hitachi to develop a metal-ferrite recording head that provides better head surface contact to read the densely packed particles. Other companies, chiefly Sony, Toshiba, and Matsushita, have issued technical papers and developed prototypes. But don't expect to see the perpendicular disk on store shelves for awhile. Perpendicular recording has been on the drawing boards for several years, but still hasn't proven to be as cost effective or as easily produced as traditional magnetic media, says Maxell's David Berry.
"There continues to be a lot of work by the media and drive people; however, the progress has been much slower than anticipated," he says. "It's a new technology, and the big thing today is the cost of storing per byte on any sort of media. It's a price-performance question right now as to whether it can be made cost effective. We feel that, down the road, it will be the media and drive of the future."

James Porter, head of the market research company, Disk/Trend, Inc., agrees that there's plenty of work ahead before perpendicular recording is durable and cost efficient enough to work.

0n another front, computer users are finding that Win-chester-style hard disk drives are increasing in performance as they drop in price. Lower prices and ease of use-especially important with today's increasingly integrated, memoryhungry applications-are making hard disks attractive even to casual computer users.

A hard disk spins within a drive, much like a floppy, but at faster speeds ( \(3,600 \mathrm{rpm}\), for example). However, hard disks have traditionally been nonremoveable, and their recording heads don't actually touch the disk-instead, they float just above the surface. In the past, hard disks also cost thousands of dollars, were quite sensitive to dust and smoke, and were prey to "head crashes" that could ruin the whole disk.

Improvements in technology are now bringing prices down, sometimes well below a thousand dollars. In addition, new \(31 / 2\)-inch hard drives are being introduced along with the standard 8 -inch and \(51 / 4\)-inch models. These new systems are less prone to head crashes, have fewer problems with dust and smoke, and pack as much data into their systems as the older models.

Prices for hard disks in the 10 or 20 -megabyte capacities range from \(\$ 400\) to \(\$ 1,500\) depending on access time, capacity, and other fea-

A new hybrid data storage device for IBM PCs and compatibles, the Clasix DataDrive Plus Series from Reference Technology combines a 550-megabyte CD-ROM optical disc player in the same box with a 10- or 20-megabyte Iomega Bernoulli Box removable magnetic cartridge.

tures. Some 300,000 of the \(31 / 2\)-inch hard drives were shipped in 1985, while about three million \(5^{1 / 4}\)-inch hard drives (under 30 megabytes) shipped worldwide during the same period. The numbers for \(31 / 2\) inch hard disks should increase appreciably during 1986, notes Porter.

Related to hard disk drives is a relatively new product, the Bernoulli Box from Iomega Corp. The Bernoulli Box actually floats its disk on a cushion of air within the drive, and also allows the disk to be re-moved-hence, it offers the portability of a floppy with the storage capacity of a hard disk. The floating disk also cuts down on the potential for destructive head crashes and the problems of dust and smoke.

Some computer experts believe that by the year 2000, the days of magnetic computer data storage may be only an historical footnote. Major advances in the use of lowpower lasers in audio and video players are being quickly applied to computer technology. One of the hottest consumer electronics items in recent years is the audio compact disc (CD). And later this year, computer users will get a chance to see what CD laser technology can do when linked with a computer-virtually any computer-as a CDROM storage device.

The basic principle of CD ROMs is similar to the audio CD. A low-power laser beam reads microscopic pits that have been burned
into the disc itself. These pits-representing a series of ones and ze-ros-contain the data that in a magnetic medium would be formed by the arrangement of magnetic particles. The 4.7 -inch CD-ROM discs contain a whopping 550 megabytes of data per disc. The first applications are likely to be encyclopedias, such as the nine-millionword Academic American Encyclopedia, a 21 -volume reference work that fits on just a quarter of one CD-ROM disc.

The biggest problem with CDROM technology at this point is that the devices are read-only. Unlike the magnetic particles on a floppy or hard disk, once the pits are burned into the surface of a CD, they can't be altered. But that limitation is already being challenged in the labs.

Sony recently announced a writeable 12 -inch optical disc system that can hold up to 3.2 gigabytes of information. The disc is composed of two metallic elements sealed in a polycarbonate plastic. The laser beam writes information on the disc by turning the elements into an alloy which has different reflective properties. "This directseal method is more reliable and less costly than melt-type or bubble formation methods, which form gases during the writing process," says Robert Mesnik, Sony Information Products product manager. "The direct-seal method has a simple structure with no air spaces
which can cause degradation of information over time."

This is a form of WORM (Write-Once, Read-Mainly) storage technology which offers highdensity storage options for a variety of markets. The next step, however, is to create an optical technology that allows a laser to repeatedly write information on the same disc. Although not yet fully developed, an eraseable, reuseable \(51 / 4\)-inch optical disc has been announced by Maxell for distribution in 1987. But for now, CD-ROMs will remain read-only reference and archival storage devices.

One of the first CD-ROM models debuting in 1986 is Toshiba's XM-1000 drive, which will be able to access digital computer data and also play music-that is, it will be both an audio accessory and a computer peripheral. The unit will have a storage capacity of 600-680 megabytes and may enter the retail market at close to \(\$ 1,000\). Sony will also market its CDU-1 CD-ROM player in 1986.

Five years ago, few computerists could have predicted how fast and how far data storage devices would come by the mid-1980s. Just as microcomputers themselves continue to grow in capability and diminish in price, so too will their storage devices expand to accommodate bigger memories, more complex integrated software, and as-yet unheard of applications. ©

\title{
And you can start by actually building NRI＇s 16－bit IBM－compatible computer．
}

You can create your own bright，high paying future as an NRI trained computer service tech－ nician．The biggest growth in jobs between now and 1995，according to Department of Labor pre－ dictions，will occur in computer service and repair where demand for trained technicians will double． There is still plenty of room for you to get in on the action－if you get the proper training now．

\section*{Total computer systems training，only from NRI}

To learn how to work on computers，you have to get inside one．And only NRI takes you inside a computer，with total systerms training that gives you hands－on experience with computers， peripherals，and software．As part of your training，you＇ll build a Sanyo MBC－550－2，which experts have hailed as the＂most intriguing＂of all the new IBM－compatibles．

Even if you＇ve never had any previous training in electronics，you can succeed with NRI training．You＇ll start with the basics，rapidly building on the fundamentals of electronics until you master advanced concepts like digital logic， microprocessor design and computer memory． You＇ll probe into electronic circuits，using the exclusive NRI Discovery Lab \({ }^{\odot}\) and professional Digital Multimeter，that you keep．

\section*{Learn to service today＇s computers}

You＇ll assemble Sanyo＇s intelligent keyboard， install the power supply and disk drive，and attach the high resolution monitor－all the while performing hands－on experiments and demon－ strations that reinforce your skills．

As you complete your Sanyo，you grasp the ＂secrets＂that qualify you for a new career．You＇ll
learn to program in BASIC and machine language． You＇ll use utility programs to check out the Sanyo 8088 microprocessor（the same chip used in the IBM PC）．And you also get over \(\$ 1,000\) worth of software，including WordStar and CalcStar．

Learn the basics at home
Most importantly，you＇ll understand the prin－ ciples common to all computers．Only a person who fully understands all the fundamentals can hope to be able to tackle all computers．NRI makes sure that you＇ll gain the knowledge and skills to maintain，troubleshoot and service computers．

With NRI training，youll learn at home on your own time．That means your preparation for a new career or part－time job doesn＇t have to interfere with your current job．You＇ll learn at
your own pace，in the comfort and convenience of your own home．No classroom pressures，no rigid night school schedules．You＇re always backed up by the NRI staff and your instructor． who will answer questions，give you guidance and be available for special help if you need it．

\section*{Send for free NRI catalog}

Let others worry about computers taking their jobs．With NRI training，you＇ll soon have computers making good paying jobs for you． Send the coupon today for NRI＇s 100－page catalog，with all the facts about computer train－ ing．If the coupon is missing，write to NRI Schools， 3939 Wisconsin Ave．，Washington，D．C． 20016.

\section*{The}

Kathy Yakal, Assistant Features Editor

Perhaps you already have some "smart" appliances in your home-a coffeepot that comes on automatically at a preset time every morning; a clothes dryer that senses what kind of fabric is being dried and acts accordingly; lights that turn on at dusk and off at dawn to discourage burglars when you're out of town; or a microwave oven that does everything but get in the car and drive to the grocery store.

The next step, it would seem, is to have all of these individual appliances controlled by a central unit, allowing you to talk to them through one keyboard, and which might even let them communicate with each other. The efforts of several manufacturers toward standardization is bringing this sciencefiction scenario closer to home.

Many different home control units are now available. Some work through a personal computer and others are stand-alone units. They range in price from a few hundred dollars to a few thousand, and vary in the degree of technical expertise required to install them. Some are simple systems that work through existing household wiring via inex-
pensive plug-in modules. Others require some knowledge of programming and skill with a soldering iron, but are suitable for more sophisticated applications. Despite these different features, the three most common functions of these systems are appliance control, energy management, and home security.

Home control can be a full-time job for a computer, especially if you're using it to manage energy consumption. So unless you bought your computer specifically for home control, you're limited to buying a stand-alone unit or a second computer, either of which can be major investments.

Several home-control systems have been designed for the reasonably priced Commodore computers. You can still pick up a discontinued VIC-20 for under \(\$ 100\) at some stores, and a Commodore 64 for under \$150. Dedicating such an inexpensive machine to one major function has proven very appealing to both manufacturers and consumers.

For instance, the \(X-10\) Powerhouse is a very easy-to-use, inexpensive home control system that
runs on the Commodore 64. The package consists of an interface box that plugs into the computer and software that runs the system. Up to eight different appliances can be set to turn on or off at specified times. The appliances must be plugged into modules available directly from X-10 USA for \(\$ 16.95\) each, or similar modules found at many electronics or hardware stores. (BSR modules are the most common.)

No programming knowledge is necessary to use the X-10's software. The opening screen shows nine icons representing different rooms in a house. After choosing a room, you "install" your own icons to show where appliances in your own house are. Then you simply set up a schedule for turning things off and on. The only time the system ties up the computer is when you're initially setting up or changing the schedule, so you can continue to use your computer as you normally would.

The \(\chi-10\) Powerhouse is also available for the Apple IIe and IIc, Macintosh, and IBM PC series. The Macintosh version lets you draw your own house plans with MacDraw and MacPaint instead of using the boilerplate menu. All versions retail for \(\$ 150\). And if you want to do more than simply control appliances, additional modules and controllers include a burglar alarm interface, a thermostat setback controller, a telephone responder (which lets you control your home from any phone), and a heavy-duty 220 -volt appliance module.

Many of the modules that work with the \(\mathrm{X}-10\) are also compatible with a home control system called HomeMinder, from General Electric. The HomeMinder software also dis-
plays graphic icons to help you set up the system. But unlike the \(\mathrm{X}-10\), the HomeMinder is a stand-alone unit that plugs into any color TV. Suggested retail price is \(\$ 499\). GE also sells a 25 -inch color TV with the home control unit built-in for \$1,200.

Savergy, Inc., markets two home control units compatible with the Commodore 64 and VIC-20. The PowerPort, which sells for \(\$ 99.95\), can control up to eight small appliances. The CIM 112, selling for \(\$ 479\), can handle larger appliances such as washing machines and water heaters.

Genesis Computer Corporation also has a line of inexpensive home control units for the Commodore 64 and VIC-20. The VIController (\$69.95) uses BSR-type modules to automate lights and small appliances. COMsense (\$69.95), used in tandem with the VIController, lets you set up a home security system by hooking up the computer to switches on doors and windows. It can also be programmed to sense things like temperature or moisture levels in the air or ground, which would signal the VIController to turn on the lawn sprinkler or turn off the heat.

The COMclock (\$69.95) is a battery backup for the system. It automatically reboots the software used by the VIController if there is a power interruption. Super Schedule Plus is a software package that integrates the operation of all three products. (COMsense and COMclock are compatible with Savergy's products.)

The Energy Manager, from Powerline Software, does not actually control appliances, but is a software package that helps keep track of and analyze energy use in homes and small office buildings. It runs on the Commodore 64 and retails for \(\$ 59.95\).

To justify the expense of adding a controller to your collection of home electronics, there has to be some reward. If it's primarily a home security system, or even just a unit that turns lights on and off, the rewards are obvious: security and convenience.

Another tangible reward can come in the form of monetary savings, if you buy a system geared

toward economizing your energy usage. John Helwig, of Jance Associates, Inc., has designed an inexpensive, easy-to-install system that can save substantial amounts of energy, especially if you have an allelectric home.
"The utility companies are in a bind," says Helwig. "They sell electric, and the electric they sell comes from the plants they build. Of course, they want to get away from the idea of building more plants. They want to sell you more electric, but they want to sell it to you at offpeak hours, because it is actually cheaper for them.
"During the day, when everyone wants power, they have to run their most inefficient plants. They only run their most efficient plants at night. So although they want to sell more power-like any company, they want to sell more of their product-they want to sell it in offpeak hours. So the kick in it for them is, very simply, if they can get their customers to use electric at night, it's to their advantage."

Helwig's energy management system, REDUCE (Reduction of Electrical Demand Using Computer Equipment), takes advantage of the time-of-day rates offered by many utility companies. (By lowering the hourly rates in evenings and on weekends, time-of-day rates encourage people to limit their heaviest electric use to off-peak hours.) REDUCE shuts things down during peak hours to make the most of these lower rates. In Helwig's own home, the system cut his electric bill by 40 percent last year.

Helwig's system so impressed Pennsylvania Power \& Light that the utility company is test-marketing it
with a group of consumers who have a wide variety of house sizes and lifestyles (and no computer background). The testing is designed to see how much money REDUCE can save, and whether it creates any inconveniences.

Compatible with the Commodore 64, REDUCE costs \(\$ 250\). In addition, Jance offers a Security Control System-a home security system with some home control features-for \(\$ 195\) (wired version) and \(\$ 349\) (wireless). It works on the 64 and VIC-20.

Allhome control systems have one thing in common. They must take analog infor-mation-anything read according to a scale, like degrees, volts, and pounds-and convert it into the digital information that computers can understand.

One such converter is the ADC-1 Data Acquisition and Control System (\$449), from Remote Measurement Systems. It can be used with any RS-232-compatible computer, including the Commodore 64.

One application for an analog-to-digital converter is thermostat control. If the temperature outside drops considerably, a house takes longer to warm up. The ADC-1, using a smart thermostat program, wouldn't let it cool down as much, so it costs less to reheat it. Or if the ADC-1 is connected to security sensors and it detects a back window vibrating, it might wait to see if the window vibrates again. If it senses another vibration, or if the window breaks, the unit might turn on a sequence of room lights to make it appear that someone is walking in that direction to investigate.

The ADC-1 is currently being used for a tremendous variety of purposes in homes and business across the country. Amana, a major appliance manufacturer, has reduced the time required to test room air conditioners from 20 min utes to 2, using an ADC-1 and Commodore 64. A southern California architect uses the system to manage the components of a cus-tom-designed solar heating system. And an arboretum on Bainbridge Island, Washington, uses it to keep track of meteorological measurements.

TAP
of the \\ THE Pow Commodore ER
128
}

\section*{By the author of Machine Language for Beginners and Second Book of Machine Language}

\section*{128 Machine Language for Beginners Richard Mansfield}

One of the bestselling computer books ever has now been completely revised for the Commodore 128. Most commercial software is written in machine language because it's far faster and more versatile than BASIC. This new edition of Machine Language for Beginners is a step-by-step introduction to 8502 machine language programming on Commodore's 128 computer.

The book includes everything you need to learn to effectively program the 128: numerous programming examples, memory management tutorials; a complete description of the many Kernal routines and other new 128 features; numerous hints and programming techniques; and a dictionary of all major BASIC commands and their machine language equivalents. It also includes a high-speed, professional-quality, label-based assembler, optimized to take advantage of the speed and extra memory of the 128.
0-87455-033-5
\$16.95
Like the other top-quality books from COMPUTEI, 128 Machine Language for Beginners brings you ready-to-use information in a clear, lively style that makes learning easy and enjoyable, whether you are a beginner or an advanced computer user.

An optional disk is also available which includes the assembler and example programs in the book. The 128 LADS Disk is fully tested and ready to load on the Commodore 128. It costs only \(\$ 12.95\) and saves you hours of typing time.

Order your copy of 128 Machine Language for Beginners and the LADS Disk today. Call toll free 1-800-346-6767 (in NY 1-212-887-8525) or mail your payment (plus \(\$ 2.00\) shipping per book or disk) to COMPUTEI Books, P.O. Box 5038, F.D.R. Station, New York, NY 10150.

COMPUTE! books are available in the U.K., Europe, the Middle East, and Africa from Holt Saunders, Ltd., 1 St. Anne's Road, Eastbourne, East Sussex BN21 3UN, England and in Canada from Holt, Rinehart, \& Winston, 55 Horner Avenue, Toronto, ON M8Z 4X6.

All the exciting, entertaining, and educational games, applications, and utilities from COMPUTE! magazine are now available on disk
}

\section*{for your Commodore, Atari, Apple, or IBM personal computer. \\ The COMPUTE! Disk}

A new COMPUTE! Disk is published every month, rotating among the four major machines covered by COMPUTE!: Commodore 64 and 128; Atari 400/800, XL, and XE; Apple II-series; and IBM PC, PCjr , and compatibles.

Every three months you can receive a disk with all the quality programs from the previous three issues of COMPUTE! that will run on your brand of computer.

Like the popular COMPUTE!'s Gazette Disk, the COMPUTE! Disk is ready-to-load and error-free. It saves you valuable hours of typing time and eliminates typing errors.

With a subscription, you will receive one disk every three months for a total of four disks a year-for only \(\$ 39.95\). That saves you \(\$ 20\) a year off the singleissue cost.

Or you can order individual issues of the Disk for \(\$ 12.95\) a disk plus \(\$ 2.00\) shipping and handling.

Remember to specify your type of computer when ordering the COMPUTE! Disk. You'll find more information about this month's COMPUTE! Disk in this issue. (Note: You'll need the corresponding issues of COMPUTE! magazine to use the Disk since the disk will have no documentation.)

For fastest service when ordering a subscription to the COMPUTE! Disk, call toll free 1-800-247-5470 (in Iowa 1-800-532-1272).

For more details or to order individual issues of the COMPUTE! Disk, call our Customer Service Department toll free at 1-800-346-6767 (in New York 212-887-8525).
Please allow 4-6 weeks after placing an order for your first disk to arrive.

\section*{ITALSO RUNS ON 64K.}

Serious runners know it takes more than great running shoes to improve performance. It takes knowledge. Now Puma gives you both. With the RS Computer Shoe. The first training shoe to combine advanced. footwear technology with computer technology.

The RS Computer Shoe has a custom-designed gate array built into its heel. This computer chip records your run, then communicates the results to any Apple IIE, Commodore 64 or 128 , or IBM PC computer.
A software program included with the shoe automatically calculates your time, distance and calories expended. Then graphically compares them to past performances and future goals.

The RS Computer Shoe from Puma. We're so out front in technology, we put computers in the backs of our shoes.
Apple is a registered trademark of Apple Computer, Irc: Commodore 64 and 128 are trademarks of Commodore Computer Systems: IBM and IBM PC are registered trademarks of IBM.

The low cost of Commodore home computers prompted designers at Proteus Electronics, Inc., to develop the Simple Interface Data Acquisition System (ADAC) for the Commodore 64, 128, and VIC-20. The system consists of an interface (\$34.95) and an analog data acquisition conditioner (\$64.95). The system can digitize up to 16 channels of analog signals, making it appropriate for functions such as heating, cooling, solar control, voltage measurements, robotics, and weather station monitoring. An Apple version should be available by the time you read this for about \(\$ 150\).

For a home control unit to appeal to many people who don't own personal computers, ease of installation and use is crucial. Manufacturers realize that, and continue to work toward that goal.

Voice recognition may be one method of operation that could appeal to people not enamored of keyboards. Magician Gus Searcy and West German programmer Franz Kavan have developed a
home control system that uses voice recognition. Marketed by Mastervoice, the system is called Sidney, the Butler in a Box. Working through existing household wiring, Sidney can dim and brighten lights, answer the phone, act as a security guard, and turn household appliances off and on-all at the sound of its master's voice. A stand-
alone unit, Sidney retails for \(\$ 1,195\).
It's been predicted that eventually we'll all have some kind of universal controller in our homes, a unit that ties together all of our electronic appliances, entertainment equipment, and telephones. Fortunately, we can get a taste of the future right now with the easy-to-use products already available.

\title{
Switchbox
}

\author{
Todd Heimarck, Assistant Editor
}

Here's a challenging game of strategy that looks easy at first, but takes time to master and permits many variations. The original program is written for the Commodore 128. We've added new versions for the Commodore 64, Apple II, eight-bit Atari computers, IBM PC/PCjr and Atari 520ST, as well as an Amiga version with speech and stereophonic sound effects.

Playing "Switchbox" is like putting dominos in place for a chain reac-tion-either you're setting them in position or you're knocking them over. Winning requires skill and a sense of when to go for points and when to lay back and wait for a better board. The goal is simple: You try to score more points than your opponent by dropping balls into a box full of two-way switches. Each switch has a trigger and a platform. If the ball lands on an empty platform, it stops dead. But if it hits a trigger, it reverses the switch and continues. In many cases dropping a single ball creates a cascading effect-one ball sets another in motion, which sets others in motion, etc., all the way down.

Type in the program listing for your computer, and save a copy before you run it. If you're using a Commodore 128, enter the 128 version in 128 mode (not 64 mode). The Atari version runs on any eight-bit Atari computer with at least 16 K of memory. The Apple II game works on any Apple II machine, under either ProDOS or DOS 3.3. The IBM PC/PCjr version requires BASICA (PC) or cartridge BASIC ( PCjr ), and a color/graphics
adapter on the PC.
The Amiga version of Switchbox requires 512 K of memory and Amiga BASIC by Microsoft (not ABasiC, the version supplied with a few very early Amigas). If you have only ABasiC, contact your dealer about getting an upgrade to Amiga BASIC. Before running the program, make sure that the Amiga's display is set for 80 columns of text (if it isn't, the numbers printed on the screen won't match the rest of the display). If you've previously changed the display to 60 columns, open the Preferences icon and change it back to 80 , then close Preferences, activate BASIC and run the program as usual.

Since the Amiga program doesn't use line numbers, we've placed small arrows in the listing to show you where each line ends. Don't try to type in the arrows: There's no such character in the Amiga's character set. Wherever you see an arrow in the listing, press Return (or move the cursor off that program line) to enter the line. It's important to include the colon (:) that appears after program labels (Nextround:, Setup:, and so on). If you accidentally omit the colon, you'll make it impossible for the computer to use that label correctly.

Before typing in the 520ST version you must turn off the buffered graphics by clicking on Buf Graphics in the Run menu. You can be in either medium or low resolution mode when typing in the program; but before running it, you must be in low resolution mode. This can be done by selecting Set Preferences from the Options menu on the desktop and clicking on Low.

\section*{A Box Of Switches}

Switchbox is a tale of twos: Each switch has two parts, two positions, two states, two paths in, and two paths out. The two parts are the platform and the trigger. A switch can lean to the left (platform left, trigger right) or to the right (platform right, trigger left):

Figure 1. Trigger States

The trigger is weak, and always allows balls to pass. But the platform is strong enough to hold a single ball. So the platform either holds a ball-it's full-or it does not and is empty. When a ball sits on a platform, the switch is said to be loaded, or full.

\section*{Figure 2. Loaded Trigger}

Figure 2 shows a full switch over two empty switches. The platform holds a ball and leans to the left. The trigger extends to the right. Note that the switch on top has two pathways leading in, the left path and the right, and that the right path leading out is the left path into
one of the switches below. The left path of the top switch leads into the right path of the other, the switch below and to the left. If you drop a ball down the righthand path, it hits the trigger and flips that switch to the right. Then it continues down, hits the lefthand trigger below and flips that switch as well.

In the meantime, the ball on the platform is set in motion (when the switch is flipped) and then hits the trigger. The top switch is reset to point to the left. The second ball then drops a level to the platform below, where it stops. The playing field is composed of five levels, with four switches in the first level and eight in the bottom level. At the beginning of the game, there are no balls on the field-all platforms are empty-and the position of each switch is chosen randomly.

\section*{Moving Down The Path}

Players alternate dropping balls into one of eight entry points. These balls (and others) may or may not make it all the way through the switchbox, to one of the 16 exit paths. Balls fall straight down (with one exception), so a ball's movement is always predictable. When it hits an empty switch, one of two things can happen. If it lands on the empty platform, it stops dead in its tracks. But if it lands on a trigger, it falls through to the next level below.

Moving balls always make it through loaded switches. Triggers allow balls to continue, and move the switch to the other position. If it's loaded, the dead ball on the platform is put into motion and it hits the trigger that just moved over. This makes the switch go back to its original position, but with an empty platform. So when a ball hits the trigger of a loaded switch, its motion continues unabated. The switch moves, the ball on the platform begins to fall and it hits the newly placed trigger. The newly emptied switch moves back again, and the two balls drop to the next level.

There's one more possibility: a ball dropping onto a platform that already holds a ball. A platform can't hold any more than one ball, so when this happens one of the balls slides over to the trigger. So
the ball does not move straight down-it slides over to the next pathway. This is the exception to the rule that balls drop in a straight line. Of course, when the ball hits the trigger, the switch changes position, causing the other ball to drop and hit the trigger.

\section*{The Chain Reaction}

At the game's start, all platforms are empty, so four of eight entry paths are blocked. Remember that your turn ends when a ball hits an empty platform and stops. As the switches fill up, the chances increase that a ball will descend through several levels. The goal is to score points by getting balls to pass all the way through the maze of the switchbox. The best way to collect a lot of points is to cause a chain reaction.

A ball that hits a loaded switch from either side continues on its way. And the previously inert ball on the platform starts moving. One enters, two exit. If both of those balls encounter full platforms, four drop from the switches. The pathways are staggered, so the effects can spread outward, with more and more balls cascading toward the bottom.

Rather than taking an easy point or two, it's often worthwhile to build up layers of loaded switches. Watch out for leaving yourself vulnerable, though. Because players take turns, you'll want to leave positions where your opponent's move gives you a chance to create a chain reaction. The best strategy is to play defensively. Look ahead a move or two, and watch for an opening that allows you to score several points at once.

\section*{Four Quarters}

A game of Switchbox always lasts four rounds. In the first (equality), each exit counts for two points. Your goal is to score ten points. The second quarter has more points available, as well as a higher goal. If you look at the exits, you'll see that the further away from the middle, the higher the point value. The numbers increase in a "Fibonacci" sequence: \(1,2,3,5,8\), and so on. Each number is the sum of the previous two ( \(1+2\) is \(3,2+3\) is \(5,3+5\) is 8 , etc.). The target score in round two is 40 .

\section*{COMPUTE! Books Announces}

As computers come and go in industry popularity, we try our best to maintain a flow of excellent books for readers and users of the most popular personal computers. You'd be the first to agree that, simply because a particular computer is no longer produced, information on it is no less important to you. But we've found that when some computers lose mass appeal, or are no longer at the top of the current bestseller list, many book stores no longer wish to stock books on them.

These books become arguably more valuable to those who need them . . .
those who never got around to buying them . . . or those who have bought their personal computer second-hand, but now can't find books about it.
This sale is for you. It mixes the best of our backlist-from machine-specific to topical titles that never quite caught on-and gives you significant savings on dozens of COMPUTE! titles. Some quantities are very limited, so send in your order soon. Credit card or check with order only. Or call our toll free number: 1-800-346-6767 (in NY 212-887-8525).

Order any three from Group A for \(\$ 24.95\) (an initial savings of at least 30 percent), and receive up to three from Group B for \(\$ 3.00\) each. (A potential total savings of over \(\$ 55.00\) !) All orders add \(\$ 2.00\) shipping and handling per book up to 5 books. Over 5 books, add \(\$ 5.00\) per order.

Group A (Three for \$24.95)
First Book of Atari Graphics
Second Book of Atari Graphics
Commodore 64 Games for Kids
All About the Commodore 64, Vol. 1

\title{
Writing An Amiga Game \\ Philip I. Nelson, Assistant Editor
}

Writing "Switchbox," our first game translation for the Amiga, posed a number of interesting programming challenges and proved to be an excellent way to become familiar with Microsoft's Amiga BASIC. To show off just a few ot the machine's special features, the Amiga version of Switchbox includes fast graphics, stereo sound effects, and voice synthesis.

The first thing you'll notice about the Amiga program is that it has no line numbers. Instead, meaningful labels like Setup:, Putball: and Nextround: mark subroutines and major program divisions. To improve the program's readability, meaningful variable names like Points, Round, Column and Row have also been used in a number of cases. If you're familiar with Commodore 128 or 64 BASIC, you may find it interesting to compare one of those versions with this one. Though some routines have been repositioned, and the graphics techniques are very different, this program follows essentially the same logic as the original.

\section*{Window Management}

Before creating any graphics, you must make some basic decisions about the screen itself. The four PALETTE statements in the Setup: routine specify colors for the new screen. If these are omitted, the Amiga uses the same colors that appear when you activate BASIC. The following statement creates a window for the game screen:
WINDOW 2,"Switchbox","0

The first parameter (2), creates a new output window specifically for this program's output. If you don't create a new window, all output goes to window 1 , which is normally titled with the name of the current program. You could follow this statement with WINDOW OUTPUT 2, to direct all output to window 2. But that's done automatically when you open the window. When you close the window with WINDOW CLOSE 2 (see the Gohome: routine), output reverts to window 1 again.

The second parameter in a WINDOW statement is a string that contains the window's title.

The third WINDOW parameter, which is optional, specifies the window's size. Windows can be smaller than the actual screen. In this case, we needed a full-screen window, so we simply left out this parameter. The window automatically expands to the full size of the screen.

The fourth WINDOW parameter also is optional. It specifies the window's type-that is, the window's characteristics. Though it's often desirable to resize a window and move it around the screen, those features aren't needed for a game. To disable them, we specify a window type of 0 . This creates a window that can't be resized or moved around with the Title Bar; can't be moved from the front to back of other windows with a Back Gadget; and can't be closed with a Close Gadget. However, Amiga BASIC's normal menus are all left
active, so the player can still stop the program by choosing the Stop option from the Run menu.

In any program that includes speech, it's a good idea to include a short SAY statement at the very beginning of the program before opening any custom windows. When the Amiga encounters the first SAY statement, it tries to load the narrator device program from disk (the Amiga's speech synthesizer is implemented in software, not hardware). If it can't find the narrator on the currently mounted disk, it displays a requester box prompting you to insert the correct volume. If this happens after you've opened a new window, the requester box may appear on the original output window, which is now invisible. This can be very confusing to a new user, who may think that the system has crashed, when in fact it's just waiting for a response.

\section*{Hi-Res Graphics}

The 128 version of Switchbox draws the playfield and animates the moving figures with traditional Commodore methods-PRINTing graphic characters on the text screen or POKEing them directly into screen memory. Since the 128's text screen is divided into 25 rows of 40 characters, it's a fairly simple matter to keep everything neatly aligned. Not so on the Amiga, which in this case presents a high-resolution graphics screen 640 pixels wide and 200 pixels high. While it's possible to put characters on this screen with

In round three the numbers are a bit lower. They increase arithmetically ( \(1,2,3,4\), up to 8 in the corners). A goal of 20 points brings you to round four, where you can score big. Here the numbers are squares: \(1,4,9,16,25\), all the way to 64 at the edges. In rounds two through four, it's sometimes prudent to leave a middle path open for your opponent to score a few
points, in order to gather a high score on the big numbers to the left and right.

Each round lasts until one player has reached the goal. At that point the other player has one last turn before the round ends. It's possible to win the round on this lastchance play; watch out for barely topping the goal and leaving a chain reaction open for the other
player. An arrow points to the scoreboard of the player whose turn it is. On the other side of the screen, you'll see a number where the arrow should be. That's the goal for the current round (the Amiga version displays the goal on both sides of the screen, below the scoreboards).

Bonus points are awarded at the conclusion of each round. Four

\title{
Atari Explodes
}

> Atari's new computer serious threat to Macintosh. Will the Amiga survive?

The Atari 520 ST is a serious challenge to the Apple Macintosh and will open up a major fight in the personal computer market.

\section*{By Joseph Sugarman}

Imagine this. If I could offer you a Macintosh computer-(a computer that sells for over \$2000)-for one third the price, you might wonder.

But what if I offered you a better computer with none of the disadvantages of the Mac and what if I added new features which improved its speed and performance? That's exactly what Atari has done in an effort to grab the ball from Apple and really explode into the personal computer market.

\section*{HEADING EFFORT}

Heading the effort at Atari is Jack Tramiel-the same man who built Commodore into a billion dollar corporation, sold more computers than any other man in the world and believes in giving the consumer incredible value without sacrificing quality. The new Atari is a perfect example.

First, let's compare the new Atari ST to the Macintosh and the Commodore Amiga. Sorry IBM, we can't compare the ST to your PC because yours is almost five years old, much slower, and, in my judgement, over priced Price The cheapest you can get the Macintosh with 512 K of memory is \(\$ 1800\) with a one-button mouse, a disk drive and a monochrome monitor. The Amiga sells for \$1995 with a two-button mouse, a disk drive and a color monitor. The Atari ST sells for \(\$ 699\) with a two-button mouse, a disk drive and a monochrome monitor and for \$200 more, a color monitor. Read on.
Monitor With the Mac you can only use its 9 " monochrome monitor and with the Amiga you can only use its 12 ' color monitor. With the ST you have a choice of either a \(12^{\prime \prime}\) monochrome or high-resolution color monitor or your own TV set.
Resolution The number of pixels or tiny dots on a screen determine the sharpness of a computer monitor. The Mac has 175, 104 pixels and has one of the sharpest screens in the industry. The Atari ST has 256,000 pixels or almost a third more than the Mac. And the Atari color monitor compared to the Amiga in its non interlace mode is 128,000 pixels or exactly the same.
Power All the computers have a 512 K memory with a 68000 CPU operating with a 32 -bit internal architecture. But Atari uses four advanced custom chips which cause the CPU to run faster and more efficiently giving it some tremendous advantages. For example, it has a faster clock speed of 8 Mhz com-
pared to the Mac's 7.83 and the Amiga's 7.16. And the speed of the unit is hardly affected by the memory requirements of the monitor which in the Amiga can eat up much as \(70 \%\) of the unit's cycle time or speed. Keyboard This is the part I love. The Mac has a small 59 -key keyboard and a mouse. That's all. The 95 -key Atari has both a mouse, cursor keys, a numeric keypad and ten function keys. The keyboard looks fantastic and is easy to type on. Although the 89-key Amiga has almost all the features of the Atari keyboard, it looks like a toy in comparison. (Sorry Commodore, but that's my opinion.) Disk Drive The Mac's \(31 / 2^{\prime \prime}\) disk drives run at variable speeds-slowing down as they run. The Atari \(31 / 2^{\prime \prime}\) drives run faster at a constant speed-and quieter than any other unit.
Features The Atari ST comes equipped with the same printer and modem ports as the IBM PC-a parallel and RS232C serial port. The Mac comes only with a tiny non-standard serial and modem port. The ST has a hard disk interface capable of receiving 10 million bits per second. There are two joy stick ports and a 128 K cartridge port for smaller programs or games. It has 512 colors (for the color monitor), it has a unique MIDI interface into which you can plug your music synthesizer and record or play back your music.
Software Right now, the Mac has more than the Atari ST and the Amiga combined. The Atari is a new system but the track record of Atari's Jack Tramiel and the potential of the new unit is causing a flood of new software titles. In fact, I'll predict that eventually the Atari will have more software than the Mac. There are now hundreds of titles, from word processing to spread sheet programs, from graphics and games to data base management-all with those easy drop-down menus and windows. There's plenty from which to select now and plenty more to come.

If you think I'm enthusiastic over the ST, listen to what the press is saying. Byte Magazine just called it the "Computer of the year for 1986." Creative Computing exclaimed, "Without question, the most advanced, most powerful micro computer your money can buy." and finally, the Atari ST is the best selling computer in Europe and acclaimed, "The computer of the year," by the European personal computer press.

I am going to make the ST so easy to test in your home or office that it would be a shame if you did not take advantage of my
offer. First, I will offer the computer itself for only \$299. You will need, in addition, either one or two disk drives and either an Atari monochrome or color monitor or your own TV. If you order with your credit card during our introduction I will ship your order and only bill you for the postage and \(1 / 3\) the purchase price. I will also add a few software packages free including "Logo" -a beginners programming language, a disk for programming in BASIC and Neochrome-a graphics paint program.

COMPARE THE TWO
After you receive the Atari ST, put it next to your Mac or Amiga or even IBM. See how extremely sharp the graphics appear, discover what a perfect word processor it is, how great the keyboard feels and finally how much faster and quieter it runs.

If you're not convinced that the Atari is far superior to your present computer and a fantastic value, simply return it and I'll refund your modest down payment plus our postage and handling charges. If you decide to keep it, I'll bill your credit card account for the remaining balance and enroll you in our discount software club (a \(\$ 50\) value) that lets you buy software for up to \(50 \%\) off the retail price.

But act fast. We have only 2,000 units and 1,000 free memberships that we will offer as part of this introductory program and we are certain they will go fast. Order today.

To order, credit card holders call toll free and ask for product by number (shown in parentheses). Please add \(\$ 20\) per order for postage and handling. (lf you pay by check, you must pay the full amount but we will provide you with a bonus software package.) ST Keyboard, CPU \& Mouse(4060M) \$299 Disk Drive (4056M) 199 Monochrome Monitor (4057M) ...... 199 RGB Color Monitor (4058M) . . . . . . . . 399 Note: A list of software will come with the unit. IBM is a registered trademark of International Business Machines Corp. Commodore \& Amiga are trademarks of Commodore Electronics LTD. Apple \& Macintosh are trademarks of Apple Computer, Inc. Atari, ST \& Logo are trademarks of Atari Corp.

LOCATE and PRINT, the Amiga's character set includes no graphics characters. So 128 -style graphic techniques are useless unless you want a game screen that consists of X's, O's, and slash characters. Instead, everything must be drawn with hi-res commands like LINE, PUT, CIRCLE, and PAINT (see the routine labeled Setup:).

Repeated shapes are stored in an array with GET and then placed in several locations with PUT commands. PUT is used extensively in this game to create the moving balls, switches, and arrows, as well as to draw parts of the switchbox itself. Though it's one of Amiga BASIC's slower graphics commands, PUT is more than adequate for a game of this type and much faster than the same commands in other BASICs. Thanks to the Amiga's fast 68000 microprocessor and custom graphics chips, this version runs much faster than the original, even though no particular attempt was made to optimize the program's speed.

PUT has several different modes which determine what happens when you PUT a shape into an area that already contains graphics data. The Amiga uses XOR (exclusive or) mode for PUT unless you specify otherwise. This mode is particularly useful for animation, since if you PUT the same shape twice into the same location with XOR, it erases itself without disturbing whatever was there before. Here's a typical use of PUT with XOR:
PUT (140,5),Larrow:PUT (440,5),Rarrow
These statements, found in the Taketurn: routine, are performed on each new turn to make the player's
arrows flip back and forth. If you're not familiar with XOR mode, this code looks confusing, since it PUTs both arrows on the screen no matter whose turn it is. But we began the game by PUTting the left arrow in place when the screen was drawn. Thus, when the first turn is taken, the left arrow erases itself, and the right one appears. On the second turn the right arrow erases itself, and the left one appears, and so on. This shortcut eliminates the need for a separate routine to keep track of the arrows' display status.

\section*{Speech And Stereo Sound}

Speech and stereo sound effects may seem flashy, but the Amiga makes them quite easy to program. Amiga BASIC's SAY TRANSLATE\$ command translates any English text into quite understandable speech. And it's easy to flip sound effects from one stereo output to another by changing the final value in a SOUND statement.

If your monitor has only one speaker, you'll probably want to defeat the stereo feature so that both players' sound effects can be heard through one output. This is easy to do. The Amiga has four sound channels, numbered \(0-3\) : Channels 0 and 3 always go to the left speaker, and channels 1 and 2 go to the right. There are five SOUND statements in the program (in the routines labeled Switch:, Putball: and Score:). In each SOUND statement, the final parameter controls whether the sound goes to the left or right output. For instance, the Score: routine contains these statements:
SOUND j,1,64,Who
SOUND \(\mathbf{j}+400,1,64,3-\) Who

The program variable Who equals 0 when it's the left player's turn, and 1 on the right player's turn. Thus, when Who \(=0\), the expressions Who and 3-Who create sound in channels 0 and 3 , which both go to the left speaker. When Who \(=1\), they output through channels 1 and 2 , which go to the right speaker. To defeat the stero effect in these statements, replace Who and 3 -Who with the values 0 and 3 , or 1 and 2 , depending on which output you're using. Similar changes to the other SOUND statements will confine them to one speaker as well.

If you don't specify otherwise, SAY commands cause the program to halt until the computer finishes saying the current phrase. But at certain points in Switchbox, the computer talks "in the background" while it performs other program tasks. At the beginning, for example, you'll see it draw several graphics shapes while it pronounces the welcoming phrase. This effect is also quite simple to achieve.

Look at the first set of DATA statements in the Setup: routine: These values are stored in an integer array (Voice\%) for later use in SAY commands. Each element of the voice array controls a different aspect of the Amiga's speech, such as pitch, speaking rate, and so on. The next-to-last element in the array controls whether the program continues while SAY commands are in progress. Setting this value to 1 selects synchronous speech which proceeds in the background. Replacing the 1 with a 0 selects asynchronous speech mode, which halts program execution until the current phrase is finished.
numbers appear below the scorecards. The first is simply the total so far. The second is the total plus a bonus of the goal for the round if the player's points are equal to or greater than the goal. For example if the goal is 20 and you get 18, there's no bonus. If you score 22, the bonus is the goal for that round (20) and you'd have 42 points. The third number under the scoreboard is the difference between scores for
the rounds. If you win by two points, two is added to your score (and two is subtracted from the other player). The final number is the grand total of the first three scores and bonuses. Rounds one and three are fairly low-scoring with low goals. You may want to seed the field with extra balls during these quarters, so you can collect more points in the second and fourth quarters.

\section*{Variations}

Although the goal of the game is to score the most points, there's no reason you couldn't agree to play for low score. In a "lowball" game, you would try to avoid scoring points. You wouldn't necessarily play backwards, you would have to adjust the strategy of where to place the balls. Fill up the board as much as possible and leave your opponent in a situation where he or she
is forced to score points．
The DATA statements at the beginning of the program（the Set－ up：routine in the Amiga version） determine the goal for each round and the point values for the exit paths．You can prolong the game by doubling the goals；this also dilutes the value of a big score at the begin－ ning of a round，preventing one player from winning on the first or second turn．An interesting varia－ tion is to assign negative values to some slots．If some paths score neg－ ative points，you are forced to think harder about where the balls will drop．

In addition to the numbered keys（1－8），the plus（ + ）and minus \((-)\) keys are active．Pressing plus drops a ball at random down one of the eight entry paths．Pressing mi－ nus allows you to pass your turn to your opponent．

Once you＇ve mastered the reg－ ular game，you can add some new rules．Each player gets three passes per half，similar to the three ti－ meouts in a football game．If you don＇t like the looks of the board， press the minus key to use one of your passes．After one player has skipped a turn，the other player must play（this prevents the possi－ bility of six passes in a row）．It＇s also a good idea to make a rule that a player can＇t pass on two consecu－ tive turns．You can also give each player two random moves to be played for the opponent．In other words，after making a move，you could inform your opponent that you＇re going to give him one of your random moves and you would press the plus key．

Here＇s one more change you could make：Instead of alternating turns，allow a player to continue after scoring．When a player drops a ball and scores some points，the other player would have to pass（by pressing the minus key）．If the first player scores again，the opponent passes again，and so on until no more points are scored．

\section*{Playing Solitaire}

To drop a ball，press a numbered key（ \(1-8\) ）．If you＇re using a 128 ，ST or Amiga，the numeric keypad is convenient for choosing a move．By using the pass and random turn options，you can play against the
computer．Here are the rules for solitaire play：

1．The computer always scores first．At the beginning of every round，the computer plays random－ ly until at least one point is ac－ quired．Press the plus key for the computer＇s turn．You must contin－ ue passing（skip your turn with the minus key）until the computer puts points on the board．

2．After the first score by the computer，you can begin to play． When the computer has a turn， press the plus key for a random move．

3．Whenever you make points， you must pass again until the com－ puter scores．When the computer gets more points，you can begin to play again．This rule means you should hold back on the easy scores of a few points；wait until there＇s an avalanche available．

4．If you＇re the first to reach the goal，the computer gets a last chance．Don＇t make this move ran－ domly；figure out the best opportu－ nity for scoring and play that move for the last－chance turn．

In the interest of keeping these programs to a manageable length， no attempt has been made to pro－ vide an＂intelligent＂computer op－ ponent．Once you become familiar with the game，you might find it an interesting project to try adding some routines that give the com－ puter a rational basis for picking one move over another．

For instructions on entering these listings， please refer to＂The New Automatic Proof－ reader for Commodore＂and＂COMPUTEI＇s Guide to Typing In Programs＂in this issue of COMPUTEI．

\section*{The Works! For Commodore And Apple}

\author{
James V. Trunzo
}

Requirements: Commodore 64 or 128 (in 64 mode) with a disk drive; or an Apple IIseries computer with at least 64 K RAM and a disk drive. Printer recommended.
"Jack of all trades but master of none" is a saying that could be applied to a collection of programs entitled The Works! from First Star Software. However, the saying would reflect only upon the level of sophistication of the individual programs making up The Works!, and should not be considered a criticism of the package as a whole.

The Works! is a compendium of useful programs for computer novices by Fernando Herrera, who first gained prominence with a program entitled \(M y\) First Alphabet, winner of an Atari First Star Award. When considering The Works!, it is essential to keep in mind the audience for which it is intended.

The package is subtitled "A Complete Collection of Home Software," and that's just what The Works! is-with an emphasis on "home." It contains 13 programs divided into four main categories: Tools, Organizers, Arts, and Learning. Under the heading of Tools, you find such programs as Letter Writer, Loans \& Investments, Calculator, Weights \& Measures, and Math Formulas; the Organizers section includes Family Finances, Calendar Pad, Address Book, and Stock Portfolio; the Arts section has Graphics Painter and Music Composer; and the Learning section has Typing Teacher and Math Races.

All of the programs that make up The Works! are completely functional. However, none of them are-nor do they pretend to be-the final answer in their genre. Letter Writer, for example, is a more-than-adequate word processor for writing letters. It contains basic commands such as Move, Copy, Delete, and Insert, as well as a number of print-formatting commands. You wouldn't use it to do a college term
paper with elaborate footnotes, though.
Similarly, all the other programs in
The Works! provide a simple, working introduction to each type of software. They take advantage of the latest windowing techniques and are very easy to use. Also, there's a certain amount of integration among the programs. For example, when using Letter Writer, you can look up an entry in the Address Book program and merge it with a letter; or you can insert the result of a calculation done on the Calculator program into a report you are writing. You're also free to copy any of the programs onto a separate disk to be used apart from the rest, if you desire.

The value of The Works! lies in this: It gives new users a taste of a wide variety of programs and introduces some of the useful functions that can be performed by a home computer. Furthermore, it does so at a reasonable cost. You could pay \(\$ 100\) or more for a sophisticated financial program and then discover that you don't need it or don't like to use it. Family Finances in The Works! gives you the opportunity to try a program of this type before you invest in a more expensive package.

For those new to the world of computers and computer software, The Works! provides an easy entry into a sometimes bewildering domain.

\title{
Under Fire For Apple
}

\author{
James V. Trunzo
}

Requirements: Apple II-series computer with at least 64 K memory and a disk drive. A joystick is required for the Apple II + , but is optional on the Apple IIe and IIc. A
version for the Commodore 64 and 128 is scheduled for release this spring.

If you're a war game buff and you've been waiting for the ultimate World War II infantry combat simulation, your wait may be over. Released by Avalon Hill, Ralph Bosson's Under Fire is an innovative milestone in all areas of computerized war gaming. It's one of the best war game simulations I've ever seen.

In fact, Under Fire is more than just a game: It's a complete, open-ended system in the same vein as its board game predecessor, the award-winning Squad Leader. With the three disks that come with Under Fire-a master disk, a scenario disk, and a mapmaker diskyou can design your own scenarios as well as play the standard games.

Although Under Fire is as complex as it is realistic, it is not a difficult game to learn (though playing and playing well are two different things). An extremely well-written rule book, complete with a step-by-step scenario, helps you get under way and allows you to absorb details bit by bit as you become more immersed in the mechanics of the game.

Under Fire lets you play solitaire or against another person, using one of nine prepared scenarios or one you have created yourself. You can assume command of men and weapons from the United States, Germany, or the Soviet Union. Each infantry squad, gun, and tank is individually represented on any one of three available maps: a situational map, showing the large-scale picture; a strategic map, depicting a smaller, more detailed portion of the battlefield; and a tactical map that shows the terrain and units to a degree of detail that is hard to believe. Frankly, an entire review could be written on this program's graphics alone.

\section*{Unprecedented Flexibility}

Under Fire is so flexible that it truly lives up to Avalon Hill's boast that it's a "War Game Construction Set." When you combine the unit types, the terrain selections, the battlefield objectives, and the various orders of battle, there is almost no land engagement that cannot
be accurately simulated. That's why the nine scenarios provided are named after historical encounters; they represent types of conflicts ranging from open-field firefights to house-to-house battles. You can attack or defend objectives, recreate breakthroughs, or enter into all-out slugfests.

Lavish attention has been paid to details such as troop morale, training, supplies, skill levels, hidden units, line-of-sight fire, and animated combat. At the end of a battle, you get a complete report of men lost, men remaining, armor lost, and other statistics.

This review really just scratches the surface of Under Fire. For example, the Apple version even allows for the optional use of a Mockingboard to enhance the sound effects of raging battles. Avalon Hill and designer Bosson have created what is sure to become a standard for computerized war games in the future.

\title{
M-Disk For Atari ST
}

\author{
George Miller, Assistant Technical Editor
}

Requirements: Atari ST computer with at least 512 K RAM; extra RAM recommended.

Do you often find yourself wishing for extremely fast, temporary storage to supplement the floppy disk drive on your Atari ST? M-Disk, by MichTron, lets you set aside a portion of Random Access Memory (RAM) as a RAM disk. This area of memory is used like a disk drive, except it's much faster. By moving small, frequently used programs or data files into the RAM disk, you can speed up access and make disk-intensive programs run more efficiently. (Of course, you still have to copy the programs or files you want to save onto a real disk before ending the session because the RAM disk disappears when power is shut off.)

M-Disk is easy to use. Michtron's user manual, although small, is wellwritten. Installing the RAM disk is no problem. And since the ST's operating system (TOS) sees the RAM disk as just another floppy disk drive, transferring files from memory or floppy disk to the RAM disk is a snap.

With M-Disk, you can specify the size of the RAM disk in 12 K blocks up to a maximum of 800 K , if your ST has this much memory available. Using the standard 520ST with 512 K RAM, you can set up a RAM disk of 84 K , or 111 K if no GEM desktop accessories are loaded.

However, some larger application programs can't be used with a 512 K machine and \(M\)-Disk due to memory limitations. For instance, it was almost impossible to use M-Disk with ST BASIC because BASIC normally leaves only about 5 K free to begin with. If Atari carries through with plans to put TOS in Read Only Memory (ROM), more than 200 K RAM will be freed up for such purposes.

When TOS is available in ROM, or when you add more memory, M-Disk will become an indispensible accessory for your Atari ST.

\section*{Atari XM30 1 Modem}

\author{
Tom R. Halfhill, Editor
}

Requirements: Atari \(400 / 800, \mathrm{XL}\), or XE computer with at least 48 K RAM and a disk drive. The 1200XL requires a slight hardware modification (see text).

If you've been waiting for a (nearly) painless way to get started in telecomputing, the new Atari XM301 modem might be just the ticket. For about a quarter of what a bare-bones acoustic modem cost just a few years ago, the XM301 package includes a reliable, 300 bits-per-second (bps), direct-connect modem with autoanswer and autodial; an easy to use terminal program with full upload/download capabilities; free introductory time on popular commercial information services; and a wellwritten manual that guides you step by step through the often-confusing world of telecommunications.

Thanks to the latest modem-on-achip technology, the XM301 is just slightly larger and heavier than a pack of cigarettes. And that includes the power supply and interface, because the XM301 doesn't require a power supply and interface-it plugs directly into the Atari's serial input/output (SIO) port and draws its power from
same. This is a major improvement over early Atari modems, which forced you to buy the \$200 850 Interface Module and add yet another power transformer to the existing clutter.

Hooking up the XM301 takes just two steps. First, plug its permanently attached serial cable into the SIO port. Second, unplug the modular phone cord on your telephone and connect it to the XM301's modular jack.

The only complication is if you're using a 1200 XL computer. The 1200 XL designers wanted to discourage manufacturers from making peripherals that drew power from the computer, so they added a current-limiting resistor to the SIO port which keeps devices such as the XM301 from operating properly. Fortunately, the fix is not difficult for an Atari service technician or experienced electronic hobbyist. According to Atari, resistor R53 on the SIO port must be bypassed or replaced with a jumper. Atari recommends that you take your 1200XL into an Atari service center for this modification. (It won't affect any other operation of the computer.)

\section*{Upload And Download}

Once the modem is hooked up, you're ready to run the terminal software included in the package, XE Term. Despite its name, XE Term works on \(400 / 800\) and XL series computers with at least 48 K RAM as well as on the newer XE machines. The disk includes DOS 2.5 and an autoboot file that automatically runs XE Term when you switch on the computer.

Pop-up menus and single-keystroke commands make XE Term extremely easy to use. Yet it's not a stripped-down terminal emulator; it's actually a fairly versatile program that contains enough features to satisfy most people's telecomputing needs. Earlier Atari terminal programs, such as the TeleLink I and TeleLink II cartridges, often were criticized for their lack of file transfer functions. XE Term is a sharp departure from the TeleLink series. Not only does it allow you to upload and download files with other computers, it even provides three different protocols (file exchange schemes) for this purpose.

The simplest protocol is the ASCII transfer function. It's most often used for exchanging text files, such as documents created with a word processor. You can also "capture" any incoming text with this option and send it to the disk drive or printer. ASCII transfers don't employ any error-checking, however, so characters can get garbled if the phone line is noisy.

The second transfer protocol in XE Term is called XMODEM, a standardized scheme that is popular on many

electronic bulletin board systems (BBSs). XMODEM is somewhat slower than ASCII protocol, but it checks for transmission errors during the transfer. This makes it particularly useful for uploading and downloading such critical files as programs.

XE Term's third transfer scheme was a surprise-the A-protocol used by the CompuServe Information Service. XE Term automatically recognizes Aprotocol, so it's easy to download programs and other files from CompuServe.

The only drawback to XE Term's
file transfer capabilities is its rather small buffer-only about 14 K . Most Atari terminal programs have larger buffers. This restriction means that files longer than 14 K must be broken up into pieces before uploading or downloading.

\section*{Online Phone Book}

XE Term strikes a balance between ease of use and full-featured telecommunications. You can link up with Ataris, most other personal computers, information services, and BBSs of almost any flavor. But if the other computer is an oddball or a mainframe with unusu-

\end{tabular}
al requirements, you may need a program that provides more communication options.

To reach XE Term's Options menu, you press O from the main Functions menu (a keystroke that Atari forgot to list on the Functions menu, by the way). The Options menu pops up and lets you change the input parity (none, even, odd, or clear); output parity (none, even, odd, or set); the duplex mode (half or full); and translation mode (ASCII and Atari ASCII, called ATASCII). You can also change the left screen margin from its normal indentation of two characters.

A few convenience features make XE Term even easier to use. You can save the communication settings to disk in a configuration file so the program always boots up the way you want it to. A dialing menu lets you switch between tone and pulse dialing, store up to five phone numbers that can be dialed with a single keystroke, or dial directly from the computer keyboard. When you're establishing a connection, all telephone sounds are routed through the TV or monitor speaker. That way, you can listen to the modem dialing the number and hear any busy signals, recorded messages, or humans that may be encountered on the other end of the line.

Automatic log-on sequences can be programmed to speed up access to remote computer systems. For instance, you can tell XE Term to dial your local CompuServe access number, type a CTRL-C to get CompuServe's attention, and enter your ID number and password-all without any intervention on your part. You can also set up the modem for autoanswer mode in case someone wants to call your computer.

\section*{A Few Extras}

The 50-page manual is very well-written and contains just about everything you need to know to use the XM301 modem and XE Term. There's even a short glossary of telecommunication terms. For advanced users, a file on the XE Term disk contains technical information about the modem and its software interface. Another disk file, HANDLER.OBJ, is the modem's device driver. This makes it possible for programmers to write their own custom terminal or BBS software for the XM301.

On top of all this, you get introductory offers to online services and discount coupons that by themselves are worth more than the cost of the XM301 package. There's \(\$ 15\) worth of free time on CompuServe, a \(\$ 20\) discount for joining The Source, a \(\$ 75\) password and hour's time on Dow Jones News/

WITH THESE NEW INTRODUCTORY BOOKS FROM COMPUTE! BOOKS.
These titles will help you unleash the power inside your computer. Whether you're an experienced programmer learning a new language or a beginner just starting out, these books will show you, clearly and quickly, how to get more than you ever thought possible from your computer.

THE AMAZIWG AMIGA
The Amiga: Your First Computer
Dan McNeill
Written in a lively and entertaining style, this book teaches everything a beginner needs to know to get started quickly with the Amiga from Commodore. You'll learn about setting up the system, some of the most popular types of software, and details about the hardware.
ISBN 0-87455-025-4
\$16.95
Using AmigaDOS
Arlan R. Levitan and Sheldon Leemon
A comprehensive reference guide and tutorial to the powerful AmigaDOS-the operating system underlying the Workbench and Intuition-this book offers information useful to every Amiga owner. AmigaDOS, the alternative to the icon-based Workbench, lets you control the computer directly. Using AmigaDOS defines and illustrates all DOS commands, and shows you how to create file directories, access peripherals, and run batch file programs. You'll learn why the system prompts you to swap disks, and how to avoid "disk shufffle." The screen- and line-oriented text editors, both overlooked in the user's guide which comes with the Amiga, are explained in detail. Numerous examples and techniques show you how to use AmigaDOS to make operating your computer even more convenient. A full reference section details each DOS command, giving you easy access to the complete AmigaDOS. ISBN 0-87455-047-5
\$14.95

BRING THE ATARI ST ALIVE
Introduction to Sound and Graphics on the Atari ST
Tim Knight
The ST, Atari's powerful new computer, is an extraordinarily impressive sound and graphics machine. Easy to use, the ST can produce color graphics and sound. You'll find thorough descriptions of the computer's abilities, and the information needed to create a complete sound and graphics system. This is the perfect introductory reference to sound and graphics on the Atari ST.
ISBN 0-87455-035-1
\$14.95
LEARN C
From BASIC to C
Harley M. Templeton
This introduction to C takes you by the hand and shows how to move from BASIC to this increasingly popular language. BASIC programmers will find this approach designed just for them. Early chapters discuss C language equivalents for common BASIC statements and the similarities and differences between BASIC and C . Later chapters teach everything you need to know to write, debug, and compile programs in C .

\title{
EduCalc And NoteCard Maker
}

\author{
Karen G. McCullough
}

Requirements: Commodore 64 or 128 (in 64 mode) with a disk drive; Apple II-series computer with at least 64 K RAM and a disk drive; or an IBM PC/PCjr with a disk drive. The Apple version was reviewed.

Recent attempts to teach computer literacy have focused on familiarizing students with the software tools commonly used on personal computers. To assist that effort, Grolier Electronic Publishing, Inc. has released two programs: EduCalc and NoteCard Maker. Each is a simplified version of a popular type of software for personal computers and is aimed at junior to senior high school students.

EduCalc is a spreadsheet-a stripped-down, bare-bones version of programs like VisiCalc, Multiplan, and Lotus 1-2-3. Spreadsheets allow computers to perform sophisticated mathematical operations on large quantities of numbers. As with all spreadsheets, \(E d u C a l c\) lets you enter numbers, mathematical formulas, or text in rows and columns on the screen. Each piece of information is stored in a cell identified by a letter for the column and a number for the row. The numbers entered into the cells can be manipulated in various ways by other cells containing formulas. The result of a particular operation is displayed in that formula's cell.

EduCalc includes a tutorial which serves as an excellent introduction to spreadsheets in general as well as to EduCalc. It's simple, clear, and should make novices comfortable with the program in 15 to 20 minutes. A practice template lets you experiment with the program. Unlike more powerful spreadsheets intended for professional busi-
ness applications, EduCalc is extremely easy to use. Menus guide you through lists of options, and various functions are displayed on the screen along with advice on using them. The program does a good job of protecting you against errors.

\section*{No Shortcuts}

But there's a price for that simplicity. Where EduCalc is friendly to novice users, it may frustrate those who become more experienced with it. The program structure is rigid-there are no shortcuts.

For example, to enter a formula to add up a column of numbers, you choose Enter from the Tool menu, move the highlighted cursor to the cell where the results are to be displayed, choose Formula from the Entry menu, and press \(S\) for sum. Then you move the cursor to the first cell of the column to be totaled, press RETURN, move the cursor to the last cell of the column, and press RETURN again. It sounds easy and logical, but it's also frustratingly time-consuming if the column is 40 figures long.

There are other limitations as well. Only mathematical operations can be performed-there are no logical or lookup functions. And you can't jump directly to a specific cell on the spread-sheet-you must move there with the cursor. That can be very slow on a large sheet, because the program redraws the screen each time the cursor moves off the edge.

The EduCalc manual could use larger print, an index, and better explanations. For example, when you're saving a spreadsheet on disk for the first time, the manual says the program should ask if you want to initialize the disk. But the program doesn't. Fortunately my disk was already initialized, so I had no problem reloading the spreadsheet.

\section*{A Quick Organizer}

NoteCard Maker is a simplified database manager program. As its name implies, NoteCard Maker is intended to help students collect and organize information, especially when writing reports or term papers. It transforms the screen into a series of electronic note and bibliography cards. After entering information onto the cards, students can search for specific items or sort them in various ways.

The tutorial that comes with NoteCard Maker is just as effective as EduCalc's. Most junior high school students will be comfortable with the program after 20 minutes' work. And if they forget what to do at any point while entering information, they can simply
press CTRL-A to bring up a screenful of advice.

The process of entering information and editing the cards is simple and straightforward, and once the cards are created, there are plenty of options for using them. Both notecards and bibliography cards can be searched, sorted, viewed on screen, and listed on a printer.

Like EduCalc, NoteCard Maker's main drawback is rigid structure. There are only three options for file size, and the size can't be changed once the file is created. Nor can you alter the format of the cards or bibliographic information. Also, NoteCard Maker lets you create a duplicate file without warning that a file of the same name already exists.

Both EduCalc and NoteCard Maker are excellent programs for introducing students or novices to spreadsheets and database managers. They also may be the solution if you need a simple spreadsheet or database without a lot of complex commands. For these purposes, both programs are effective tools.

Hex is a colorful and deceptively simple game. Your goal is to change the 19 hexagonal blocks of the arena to green before your opponent-controlled by the computer-can turn them to purple. All it takes to change a block's color is to jump on it with your onscreen character. Each block changes color in a sequence displayed at the start of each level: green, then red, then purple, and finally blue before the sequence repeats. Seemingly a simple enough task.

Each of the 12 opponents you face employs a different strategy. Some opponents try to overpower you by the force of their magic, while others combine magic with cunning strategy and wisdom. If that isn't enough, at higher levels you may be confronted by several rival magicians, all working against you. You must learn the game well and plan your strategy carefully on the lower levels, because the computer becomes relentless as you progress to higher levels. There is no margin for error.

After successfully completing a round, you're offered the chance to learn a new magic spell. Each spell is costly, and you must exercise good judgment before undertaking the necessary instruction. Is the cost of the spell too high in energy points? Will it leave you too weak to face your next opponent?

Fast reflexes won't help in Hex. In fact, the key to early success is to play slowly and carefully, considering each move, much as in chess. Don't let the speed at which the computer plays trick you into making quick decisions. You're facing an opponent who is analyzing your tactics much faster than you can respond. Each rapid-fire move by the computer has a purpose; you must watch closely and try to disrupt its plans.

Hex may be one of the most challenging and fascinating strategy games yet devised for a computer. Although the game is simple to learn, you need to develop complex strategies to win consistently. You'll be amazed at how quickly your opponent ceases to be just a computer and seems to acquire distinct personality traits of its own.

\title{
Sylvia Porter's Personal Financial Planner
}

\author{
Selby Bateman, Features Editor
}

Requirements: Commodore 64 or 128 (in 64 mode or 128 mode); Apple IIc or IIe with 128K RAM; or an IBM PC/PCjr with at least 128 K RAM. One or two disk drives are also required. Printer optional, but highly recommended. The Commodore 64 version was reviewed.

For many people, gaining control of a household budget is an exercise in frustration. Where do you start? How do you organize all those daily purchases, bill payments, unexpected expenses, and (far-too-few) paychecks into a coherent picture? Faced with this confusion, many of us go from day to day and month to month with little idea how much we have, how much we owe, and what's left over for savings and longterm financial goals. This is especially critical now, when consumer debt is at an all-time high and personal savings have plummeted.

The good news is that you can bring order to your financial chaos. Sylvia Porter's Personal Financial Planner is a well-organized, flexible, and sophisticated computer program that can make a major difference in your budgeting and planning efforts. The sobering news is that you're still going to have to invest a significant amount of time and concentration to set up your personal system and then use it on a regular basis. This isn't meant as a criticism of the Personal Financial Planner, however. It's simply a reality of personal financial planning in general, whether you manage it with pen and paper or on a computer screen.

Many people will be familiar with Sylvia Porter's name. She's been a respected and popular financial adviser for years-the author of a variety of articles and books, plus a nationally syndicated newspaper column, about budgeting, financial planning and management, and economics. More recently, she's lent her name and expertise to Sylvia Porter's Personal Finance Magazine.

The editors of that magazine have contributed to the overall approach and content of the Personal Financial Planner, which is supposed to be the first module in an integrated series of financial planning and management programs from Timeworks bearing Sylvia Porter's name. The next program, tentatively scheduled for this spring or summer, is Personal Investment Planner.

\section*{Six Programs In One}

The strength of Personal Financial Planner lies in its flexibility, integration of information, and its well-planned structure. Think of Personal Financial Planner as six interrelated programs which share all of your financial information:

Transaction Manager: A program that lets you record and monitor all of your cash, bank account, and credit card transactions.

Budget Manager: A budget planning tool which automatically incorporates information from the Transaction Manager.

Asset/Liability Manager: An overview showing all that you own and all that you owe.

Income and Expense Statement: A part of the program that lets you organize and then print out income and expense statements in a variety of ways.

Balance Sheet: A similar component which allows you to arrange and print your asset and liability statements.

Financial Planner: A long-range planning guide that helps you set goals based on your income, expenses, and your changing asset/liability picture.

Pull-down menus and submenus make it quite easy to move around in the system. The documentation is clear, even for someone unfamiliar with computers.

\section*{Backups Take Time}

Before you can begin using the program, you must initialize a data disk for each of the program managers-three data disks in all. On the Commodore 64 , this initialization process requires more than a half-hour to complete. A data disk can generally store up to 1,250 transactions, so this initialization is only an occasional necessity. However, making backup copies of your data disks (an important precaution) is also time-consuming. The backup process doesn't just add new information to the backup disk; it completely rewrites the disk each time you make a backup. Because of the delay, it's tempting to skip this step now and then-risking disaster if your original disk should get lost or crash.

At least with the Commodore 64 version, there are a few instances when the manual doesn't mention that disk swaps are necessary. However,
onscreen prompts are very helpful here. And although the disk swapping can be an annoyance, the limitations lie with the 64 and 1541 disk drive, rather than with the program itself. Other computer versions, while functionally similar, have more space for information storage than the Commodore 64 version.

Once your data disks are prepared, your next step is to use the Transaction Manager to enter two-digit codes for up to five bank accounts (checking, money market, etc.) and up to ten credit card accounts, along with complete account information. As a part of this initial cataloging, you'll also set up a series of transaction/budget categories that you'll use with your various transactions. There are 14 major categories, including Income, Loans, Taxes, Groceries, Residence, Utilities, Clothing, Transportation, Insurance, Recreation, Medical/Dental, Education, Miscellaneous, and Other.

Each category has up to ten sub-categories-a total of 140 separate budget/transaction items. What's more, each can be individually tailored to your specific requirements, a very nice feature of this program.

Why all of those categories and codes? If Personal Financial Planner was just a checkbook balancing program or a simple budget package, little crossreferencing would be required. But each of the categories you establish can be transferred among the Transaction, Budget, and Asset/Liability managers. Hence, the computer must have a good way of keeping track of each item. This is also important when you later want the program to find and print (on screen, paper, or disk) information on individual accounts, credit cards, or subcategories. Once you've set these up and used the program a couple of times, you'll find you're comfortable with the structure. And you can easily generate a printout of the different categories and codes for quick reference.

\section*{Calculator And Notepad}

The initial effort it takes to establish budget categories is the most timeconsuming aspect of Personal Financial Planner. Once that's done, much of the program transfers information automatically, or with just a few keystrokes. Templates automatically appear on the screen, letting you add, delete, and alter virtually any part of your budget. The program also lets you include information on automatic transactionsthose recurring accounts such as rent, house payments, or loans-so that each month you don't have to enter all of the information by hand.

Among the many features are procedures for monthly reconciliation of

bank statements; searching for, changing, and printing out almost any part of your transaction, budget, or asset/liability data; automatically updating budget goals versus budget realities; setting up graphs and charts to show important aspects of your budget; tracking your financial inventory; and using financial planning worksheets that can be compared and contrasted with past, present, and future financial information.

There are many nice touches in Personal Financial Planner. In addition to the flexibility within each of the manager sections, there's a calculator and a notepad which can be called up at anytime. Also, you can search and modify your data, print out checks, track and print out tax information, and produce custom-tailored financial statements.

Timeworks and Sylvia Porter have created a serious tool with which individuals and families can track just about any aspect of their finances. But for the program to be truly useful, you'll have to make a commitment to keep your transaction information up to date. And that means spending as much as an hour per week (sometimes more, depending on what you're doing) working with the Personal Financial Planner.

If you devote this time to using the program, you'll have a clearer picture of your financial status than ever before; your budgeting will be tied in with your daily transactions; and you'll find yourself planning for the future with concrete information. For those who have trouble budgeting, tracking their transactions, and planning toward financial goals, Sylvia Porter's Personal Financial Planner can be an excellent investment.

\section*{The 1O5O DUPLICATOR IS HERE...}

\section*{THE 1050 \& 810 DUPLICATOR: The most powerful diskdrive copy system ever developed for the ATARI.}

March 1st.

\section*{The only Copy System You will ever need! \\ What will it do?}
-The main purpose of the Duplicator is to copy disksl You will be able to copy just about any disk! The copies you make will run on any Atari drive. The Duplicator need not be present to run your backup copies. The Duplicator is fully automatic. You need only insert source and destination disks. Custom formats will be read and in turn reproduced on the backup copy disk. Our device will reproduce any custom format or heavily. copy guarded scheme, bad sectors, double sectors, 19 through 24 sector format will present no problem to the Duplicator.
-You will still have single density, and double density. When you have a Duplicator installed in a 1050 drive that drive will be turned into true double density. You will have twice the disk storage. Your drive will be compatible with other double density drives as The Rana indus. Percom, etc

\section*{HARDWARE POWER}

Fully Compatible with the XL \& New XE Series.
-High speed read \& write. Your disk drive will read and load all of your software, saving wear and tear on your drive. The 810 and 1050 drives now read one sector at a time. This is slow and inefficient. With the duplicator installed you will be and inefficient. With the duplicator installed you will be able to read eighteen sectors in the time
standard, unenhanced drives to read one.
- Included with every Duplicator will be user friendly disk software. A simple, menu driven program will allow you to copy all of your software. A Duplicator enhanced drive will be a SMART drive. We plan to write many new and exciting programs that chi onlybe run on an enhanced drive, eg sending a copy-guarded disk over the phone since the copy-guarded disk over the phone. Since the can be made available to you on disks, should the need arise. No further hard ware changes, whould the needed The Duplicator comes with a full hardware and needed. The Duplicator comes with a full hardware and
software guarantee. sottware guarantee.

\section*{EASY 5 MINUTE INSTALLATION}

NO HARM TO YOUR DRIVE OR INCOMPATIBILITY PROBLEMS CAN EVER ARISE AS A RESULT OF THE INSTALLATION OF OUR DUPLICATOR. IMPORTANT: Only a hardware device like the DUPLICAIOR can backup heavily copy-guarded disks. Don't be fooled by software programs that claim to do this.

Even better, if you print a SpeedCalc file to disk (see below), you can then merge it with a word processing document created with SpeedScript, COMPUTE!'s popular word processor (see COMPUTE!, May 1985, or SpeedScript: The Word Processor for Atari Computers, published by COMPUTE! Books).

Working together, SpeedCalc and SpeedScript make a powerful team. You can merge a chart of sales figures into a company report, create a table of scientific data for a term paper, and manipulate numeric information in many other ways. In a sense, a spreadsheet program brings to arithmetic all of the flexibility and power that a word processor brings to writing.

\section*{Preparing The Program}

Although Atari SpeedCalc is small in comparison to similar commercial programs, it is one of the longest programs COMPUTE! has ever published. Fortunately, the "Atari MLX" machine language entry utility makes it easier to type a program of this size. Be sure to carefully read the Atari MLX article elsewhere in this issue before you begin. Here are the addresses you need to enter SpeedCalc with Atari MLX:
Starting address: 8192
Ending address: 16813
Run/Init Address: 8192
Next you'll be asked "Tape or Disk." SpeedCalc requires a disk drive, so type D. MLX will ask "Boot Disk or Binary File." Press F to select the Binary File option. (Although you could save SpeedCalc as a boot disk, it makes no sense, since such a disk cannot contain DOS, and DOS is necessary for fileoriented disk access.)

The screen then shows the first prompt, the number 8192 followed by a colon. Type in each three-digit number shown in the listing. You do not need to type the comma shown in the listing. MLX inserts the comma automatically.

The last number you enter in each line is a checksum. It represents the values of the other numbers in the line summed together. If you type the line correctly, the checksum calculated by MLX and displayed on the screen should match the checksum number in the listing.

If it doesn't match, you have to retype the line. MLX is not foolproof, though. It's possible to fool the checksum by exchanging the position of the three-digit numbers. Also, an error in one number can be offset by an error in another. MLX will help catch your errors, but you still must be careful.

If you want to stop typing at some point and pick up later, press CTRL-S and follow the screen prompts. MLX will ask you for a disk filename; use any legal Atari filename except AUTORUN.SYS. Remember to note the line number of the last line you entered. When you are ready to continue typing, load MLX, answer the prompts as you did before, then press CTRL-L. For a binary disk file, MLX asks for the filename you gave to the partially typed listing. After the LOAD is complete, press CTRL-N and tell MLX the line number where you stopped. Now continue typing as before.

\section*{Saving The Finished Program}

When you finish all typing, MLX automatically prompts you to save SpeedCalc. For disks with Atari DOS 2.0, 2.5 , or 3.0 , save the completed program with the filename AUTORUN.SYS. This allows SpeedCalc to load and run automatically when you boot the disk.

Because SpeedCalc requires a full 48 K of RAM in order to work, you must always disable BASIC before loading or running SpeedCalc. On an Atari 400, 800, or 1200XL, unplug the BASIC cartridge (or any other cartridge, for that matter). On an Atari 600XL, 800XL, or 130XE, unplug any cartridges and disable BASIC by holding down the OPTION button when you first switch on and boot the computer. If you forget to disable BASIC, SpeedCalc won't work correctly.

To use SpeedCalc with an Atari DOS disk, you must save or copy it on a disk that also contains DOS.SYS and DUP.SYS. Since you've saved SpeedCalc as AUTORUN.SYS, it will automatically load and run when you turn on your computer with this disk in the drive. SpeedCalc should always be named AUTORUN.SYS in order to load properly with Atari DOS. If you
want to prevent it from automatically running for some reason, you can save it with another name, then rename it AUTORUN.SYS later.

If you're using Optimized System Software's OS/A+ DOS or a compatible successor, you can give SpeedCalc any filename you like. Just use the LOAD command from DOS, and SpeedCalc will automatically run. Or you can give it a filename with the extension .COM, such as CALC.COM. Then you can start up by just typing CALC at the DOS prompt. You can also write a simple batch file to boot up SpeedCalc automatically. Some enhanced DOS packages may use so much memory that they conflict with SpeedCalc. In this case, you'll need to use Atari DOS instead on your SpeedCalc disks.

Note: The AUTORUN.SYS file on your DOS master disk is responsible for booting up the 850 Interface Module for RS-232 communications. There is no easy way to combine the 850 boot program with SpeedCalc, so you can't access the R: device while using this program. If you need to send a SpeedCalc file to a serial printer or modem, print it to disk as explained below, then print or transmit the file data as you would any ATASCII text.

\section*{The Atari SpeedCalc Screen}

SpeedCalc uses the top line of the screen as the command line. This is where SpeedCalc displays messages and asks you questions.

Screen lines 2-4 are the input buffer area. This is the work area where you enter and edit data. As you'll see in a moment, the input buffer also displays the data contained in the current cell. The work area cursor is a left arrow symbol \((+)\). After you begin to enter data, most SpeedCalc commands (except for the cursor movement keys) are deactivated until you press RETURN to enter the data into the worksheet.

The lower 19 screen lines are your window into the spreadsheet. Though the spreadsheet contains many rows and columns, only a few can fit on the screen at one time. By scrolling the screen back and forth with the cursor, you can

\section*{From the publishers of COMPUTE!}

\section*{March 1986 COMPUTE! Disk}

All the exciting programs from the past three issues of COMPUTE! are on one timesaving, error-free floppy disk that is ready to load on your Atari 400/800, XL, and XE. The March 1986 COMPUTE! Disk contains the entertaining and useful Atari programs from the January, February, and March 1986 issues of COMPUTE!. This easy-to-use disk also features SpeedCalc, the spectacular new spreadsheet program written entirely in machine language for the Atari, and the latest version of SpeedScript, the bestselling word processing program.

The March 1986 COMPUTE! Disk costs \(\$ 12.95\) plus \(\$ 2.00\) shipping and handling and is available only from COMPUTE! Publications.

For added savings and convenience, you may also subscribe to the COMPUTE! Disk. At a cost of only \(\$ 39.95\) a year (a \(\$ 12.00\) savings), you'll receive four disks, one every three months. Each disk will contain all the programs for your machine from the previous three issues of COMPUTE!.

This is an excellent way to build your software library while you enjoy the quality programs from COMPUTE!.

Disks and subscriptions are available for Apple, Atari, Commodore, and IBM personal computers. Call for details.

For more information or to order the March 1986 COMPUTE! Disk, call toll free 1-800-247-5470 (in Iowa 1-800-532-1272) or write COMPUTE! Disk, P.O. Box 10036, Des Moines, IA 50340.
move the display window to any part of the spreadsheet.

The SpeedCalc worksheet consists of 50 vertical columns labeled with letters ( \(\mathrm{AA}, \mathrm{AB} \ldots \mathrm{BX}\) ) and 100 horizontal rows numbered from \(1-100\). The rectangle where a row and column intersect is called a cell. Cells are where you store data. With 50 columns and 100 rows, the SpeedCalc spreadsheet has a maximum of \(5,000\left(50^{*} 100\right)\) cells. Due to memory limitations, however, only about a third of these can actually contain data. But you may spread out the data over all 5,000 cells if necessary, depending on the format you need.

\section*{Moving The Cursor}

Each cell is identified with the letters of its column and the number of its row. For example, the cell at the extreme upper-left corner of the sheet is called AA1, since it's in column AA and row 1. The cell below that is AA2. Moving one cell to the right from AA2 puts you in cell AB , and so on.

Your current position in the spreadsheet is shown by the highlighted cursor. The simplest way to move around the sheet is with the cursor keys, which work just as they do when you're writing or editing a BASIC program. Press

CTRL and the right cursor key to move right, and so on. Another way to move the cursor is with CTRL-H. Press CTRL-H once to "home" the cursor on the current screen: The cursor moves to the upper-left cell. Press CTRL-H twice in succession to move the cursor to cell AA1, the home position for the entire sheet.

SpeedCalc also has a goto command for moving the cursor over long distances. When you press CTRL-G, the command line displays GOTO: followed by a cursor. The cursor generally indicates that SpeedCalc is waiting for data-in this case it expects the name of the cell where you wish to go. If you enter BA88 at this point, SpeedCalc moves the cursor to the cell at column BA in row 88, adjusting the screen window as needed. Take a few moments to practice moving around the spreadsheet with all three methods; you'll be using them a lot. In a later section, we'll discuss how to change the size and format of a cell.

\section*{Keyboard Commands}

SpeedCalc offers many different commands, a few of which are entered by pressing one key. However, most commands are entered by pressing CTRL along with an-
other key. CTRL-G, as you've seen, is the goto command. CTRL-A displays the amount of free memory available, and so on.

The most drastic command is CTRL-X, which exits SpeedCalc and returns to DOS. Since this effectively erases all data in memory, SpeedCalc prompts you with ARE YOU SURE Y/N? before it shuts down. To cancel the command, simply type \(N\) (or any key other than Y ). If your Atari DOS 2.0/2.5 disk contains the file MEM.SAV (created with the CREATE MEM.SAV option on the DOS menu), you can exit to DOS and then return to SpeedCalc-however, all spreadsheet data will be lost. To restart SpeedCalc from the DOS menu after exiting, select menu option M (Run At Address), then enter the address 2000. If you're using OS/A+ or DOS XL, use RUN 2000 instead.

If you press SYSTEM RESET in SpeedCalc, you'll see the message SYSTEM RESET TRAPPED. No spreadsheet data is lost. If you're using OS/A+ or DOS XL, type RUN 2000 to return to SpeedCalc.

A few commands require you to press three keys at once. This sounds more awkward than it is in practice, since two of the three keys are OPTION and CTRL. For instance, the relative copy command

SpeedCalc Keyboard Reference

is performed by pressing OPTION-CTRL-C (hold down the OPTION console key and CTRL, then press C). The table lists all the SpeedCalc commands, and the figure shows the keyboard layout with a description of what each key does. We'll be discussing each command in more detail below.

\section*{Three Daida Types}

Before entering any data, you must know what kind of data SpeedCalc accepts. There are three different types: numbers, text, and formulas. Let's look at each type in turn.
1. Numeric data consists of num-bers-the basic stuff that spreadsheets work with. SpeedCalc has a few simple rules for numeric data: A number must be a decimal value (base 10, not hexadecimal) composed of one or more digits from \(0-9\), with an optional plus or minus sign. A decimal point is also optional. If you include any other characters in numeric input, SpeedCalc treats the entire input as text data (as explained below). Thus, the numbers 123, .001, and -65535 are valid numeric data. The number 65,535 is invalid because it includes a comma.

The allowable range for numbers in Atari SpeedCalc is similar to the range for Atari BASIC, roughly \(-1.7 \mathrm{E}+97\) to \(1.7 \mathrm{E}+98\). If a calculation produces a number outside the allowable range, you'll see the message *ERROR* in the cell containing the formula. This doesn't happen very often, since SpeedCalc won't let you enter a number more than 36 digits long, and there's rarely a need to use such large numbers unless you're tracking the national debt.

Although an input value can be up to 36 digits long, numbers in SpeedCalc calculations are accurate only to nine digits. This must be taken into account when doing any calculation involving large values. For example, you can enter the value 1122334455.66 into a cell, and the cell holds the value with no rounding. However, if you use the value from that cell in a formula, the value is rounded to nine dig-its- 112233446.00 -and the result of the calculation is accurate only for the first nine digits.

You can enter values in scientific notation by following a number with the letter \(E\) and the appropriate power of 10 . For example, you can enter \(1,234,000\) as \(1.234 \mathrm{E}+06\). However, scientific notation should generally be avoided, since values outside the Atari's maximum range may crash the program (if this happens, press RESET and rerun the program from DOS as explained above). Since there's only room for about 36 digits, unpredictable results may occur if you enter any number in scientific notation with an exponent greater than 35 ( \(\mathrm{E}+35\) ).

To see how entering numeric data works, let's enter the number 123 in cell AA1. No special commands are required to enter data: Just move the cursor to AA1 and begin typing. The left-arrow symbol shows the end of the data. While you're entering the number, it appears only in the input buffer near the top of the screen (the inverse-arrow cursor shows your cursor position). As soon as you press RETURN, the number appears in cell AA1 and the letter N appears at the upper right of the screen. The N signifies numeric, meaning that SpeedCalc has accepted the entry as valid numeric data. Move the cursor to a vacant cell, then move it back to AA1. The input buffer displays whatever data is found in the cell under the cursor. When the current cell is empty, the buffer is empty as well.

If you want to change anything during data entry, press the BACKSPACE key (BACKS on some Atari machines). BACKSPACE always deletes the character before the cursor (or has no effect if the cell is empty). Later on, we'll explain how to edit existing data.

As you've seen, pressing RETURN enters a data item into the current cell. You can also end the input by pressing CTRL and a cursor key. The data is entered as if you had pressed RETURN, and the cursor moves in the indicated direction. This feature is handy for entering a lot of data: Simply type the entry, move the cursor to the next cell, enter more data, and so on.
2. Text data is not "data" in the strict sense, since SpeedCalc doesn't
use it in calculations as it does numbers and formulas. Text data is there only to help people understand what the other data means. Text may consist of comments, titles, column headings, subheadings, or whatever you need to interpret the numbers and formulas. As an example, move the cursor to cell AA2 (just under AA1) and type the following line:
this is a piece of text data.
You can use the BACKSPACE key to erase mistakes while you're typing. When you press RETURN, SpeedCalc displays T (for text) in the upper-right corner. In this example, the cell isn't large enough to accept all the text, so only the leftmost portion appears in AA2. But even though you can't see it, all of the text is there. Move the cursor to another cell, then move it back to AA2. As soon as you return to AA2, SpeedCalc displays all the text in the input buffer area.
3. Formula data is a mathematical expression or formula. It may be as simple as \(2+2\) or as complex as your imagination (and mathematical prowess) allows. The first character in a formula must always be an equal sign ( \(=\) ). If you omit this symbol, SpeedCalc either signals an error or treats the data as text.

The true power of a spreadsheet is that a formula in one cell can refer to another cell. This is easier to demonstrate than to explain. Move the cursor to cell AA3 and type the following line:
\(=\) AA1*25.01 + @SQR(4)
As soon as you press RETURN, SpeedCalc displays F (for formula) in the upper-right corner of the screen and puts the result of the formula (not the formula itself) in AA3. If AA1 contains 123, the value 3078.23 appears in AA3. In plain English, this formula means "multiply the contents of cell AA1 by 25.01 and add the square root of 4 ."

Before we examine the formula more closely, here's a quick demonstration of what makes a spreadsheet such a powerful tool. Move the cursor back to AA1 and press CTRL-R. The command line displays the message RECALCULATION IS ON, meaning SpeedCalc now automatically recalculates the

A typical screen from Atari Speed-Calc-a compact, powerful spreadsheet program written entirely in machine language.

Atari SpeedCalc's input buffer always displays the contents of the data cell under the highlighted cursor.
entire sheet whenever you make a change. Now change the number in AA1 to 456 (simply move to the cell and start typing). The new result (11406.56) automatically appears in cell AA3. We'll explain more about automatic recalculation later.

Note that the referenced cell must contain data that SpeedCalc can evaluate: a number or another formula. If the formula refers to an empty cell, or one that contains text, SpeedCalc signals the error by printing *ERROR* in the cell containing the incorrect formula.

\section*{Mathematical Operators}

These symbols can be used as operators in a formula:
\begin{tabular}{cl} 
Operator & Function \\
+ & addition \\
- & subtraction \\
/ & multiplication \\
\(=\) & division \\
\(=\) & exponentiation \\
& equality
\end{tabular}

One factor that affects formulas is precedence, or the order in which mathematical operations are performed. In SpeedCalc, formula operators have the same precedence as in ordinary math.

The first operators to be evalu-ated-those with the highest prece-dence-are those enclosed in parentheses. Where one set of parentheses encloses another, the expression in the innermost set is evaluated first. The next operators to be evaluated are exponents. Multiplication and division have equal precedence; both operations are lower than exponentiation. Addi-
tion and subtraction have the lowest precedence of all. To take one example, SpeedCalc evaluates the formula \(=5^{*}\left(8+3^{*}-2\right)^{\wedge} 2-10 /+2\) as the value 15 , just as in ordinary math. Note how the result is affected by the plus and minus signs before the two 2 's.

\section*{Functions}

Formulas may also include any of the functions listed here:
@ABS( )
@AVE()
@EXP()
@INT()
@LOG()
@RND0
@SGN()
@SQR()
@SUM()
PI
absolute value
average of a block of cells natural exponent integer
natural logarithm
round to nearest integer

\section*{sign}
square root
sum of a block of cells
value of pi (3.14159265)
All the functions except PI begin with the @ symbol and are followed by parentheses. The parentheses of a function may contain a number or a formula. For example, the formula \(=@ S Q R(4)\) generates the square root of 4 . The formula \(=@ S Q R(A A 1)\) returns the square root of whatever value cell AA1 contains. The function @INT() generates an integer (whole number) by truncating (discarding the fractional part of) a numeric value; note that this is different from rounding (for instance, the result of @INT(-4.3) is -4 , not -5 ). Use the rounding function @RND() to round a value up to the nearest whole number.

The function @AVE() calculates the mean average of the values in a block (group) of cells. The function @SUM() calculates the
sum of a block. Both functions require you to define the block so SpeedCalc knows which cells to include in the calculation. This is done by putting two cell names separated by a colon in the parentheses. The first cell name defines the upper-left corner of the block, and the second defines the bottomright corner. To define a block in a single column, specify the top and bottom cells in the column. For instance, @AVE(AA1:AD20) calculates the average of all the cells from AA1 to AD20. The function @SUM (AA1:AD20) calculates the sum of AA1 through AD20, and so on. An error results if any cell in the block is blank or contains text data.

\section*{Editing The Sheet}

Editing is a very important spreadsheet function. The simplest way to change what a cell contains is to move to it and start typing. The old data in that cell is replaced by whatever you enter. For instance, to replace the contents of cell AA1 with the number 456 , move to that cell, type 456, and press RETURN or exit with a cursor key. Press CTRL-K (think of kill) to erase what's in the current cell. To erase everything in the sheet, press SHIFT-CLEAR. Before carrying out this drastic operation, SpeedCalc asks you to confirm it by pressing Y or N .

In some cases, only a minor change is needed. Edit mode lets you change the data in a cell without retyping the entire entry. To activate edit mode, move to the desired cell and press CTRL-E. In this mode, up and down cursor movement is disabled, and the left/right cursor keys move within the input buffer. Typing in edit mode inserts new characters in the line: Everything to the right of the new character moves right one space (unless the buffer is already full). Because all keys insert automatically, the CTRL-INSERT key combination is disabled: Press the space bar to insert a blank space. Erase unwanted characters with the BACKSPACE key or CTRL-DELETE. The CTRLDELETE combination does not move the cursor: It simply pulls the text to the right of the cursor toward the cursor position. Since the cursor keys have a different function in edit mode, you cannot use them to
end the input. Press RETURN to enter the new data and escape from edit mode.

SpeedCalc displays *ERROR* in a cell when you enter an erroneous formula. Usually this means you've made a typing error in that cell, or the formula refers to text or an empty cell. A line of asterisks (*********) signals that a number is too large to be printed in the cell. Though these messages appear in the cell area, no data is lost. You may move to the affected cell, view its contents in the input buffer, and make whatever correction is needed.

\section*{Recalculation}

Recalculation is the very core of a spreadsheet. As you know, entering or editing a piece of data makes SpeedCalc perform a calculation and put the result in the cell under the cursor. In most cases, the new data relates to data in other cells, so you'll ultimately want to recalculate the entire spreadsheet as well. This can be done manually or automatically.

To recalculate the spreadsheet manually, enter CTRL-N. SpeedCalc begins at AA1 and recalculates every cell that contains data, placing fresh results wherever needed. If you switch to automatic recalculation mode, SpeedCalc automatically recalculates the entire spreadsheet each time you enter new data or edit what exists. When you press CTRL-R, SpeedCalc changes the recalculation status and displays it at the top of the screen. If automatic recalculation was turned off before, it is now on (and vice versa). If you aren't sure which mode you're in, press OPTION-CTRL-R; SpeedCalc displays the mode without changing it. Automatic recalculation can be fun to watch in a large spreadsheet: Every time you make a change, new results appear everywhere on the screen. However, the more data your spreadsheet contains, the longer it takes to update the entire sheet. For this reason, you may want to turn off automatic recalculation most of the time, recalculating manually whenever you need to view results.

One problem with recalculation arises from the order in which
cells are calculated. Because only one cell can be calculated at a time, you must sometimes recalculate the entire spreadsheet two or three times to get correct results in every cell (this is common to all spreadsheet programs). For instance, say you have a formula in AA1 which refers to a formula in AB15. When SpeedCalc calculates AA1, it must use the existing data from AB15which is probably out of date, since the formula in AB15 hasn't been recalculated yet. To avoid this problem, you should always recalculate a sheet manually two or three times before printing it or saving it to disk.

SpeedCalc offers a number of other features. Before experimenting with them, you should spend some time typing in a hypothetical spreadsheet-perhaps a fictitious yearly budget-to become thoroughly familiar with the basic commands covered so far. Most importantly, create formulas using all the operators in different combinations.

\section*{Change Format}

The default (normal) format for numeric data is flush right with rounding to two decimal places. In other words, the number is displayed in the rightmost part of the cell, with two numbers after the decimal point. Text and formulas are also displayed flush right. SpeedCalc offers several commands for changing cell formats.
Change Format (CTRL-F). This command changes the location of data in the cell. When you press CTRL-F, the SpeedCalc command line displays the question FORMAT: LEFT, CENTER, OR RIGHT JUSTIFY?. Press L, C, or R to move the data to the left, center, or right of the cell.
Change Decimal Places (CTRL-.). SpeedCalc also lets you change the number of decimal places for any cell. The default number of decimal places is 2 , but you may change it to anything from \(0-15\). Press CTRL and the period key (CTRL-.) to change this value: SpeedCalc prompts you to enter a number from \(0-15\). If you choose zero decimal places, any number in that cell is rounded off to the nearest integer
(whole number). If you choose \(15, \mathrm{a}\) number in that cell is not rounded off at all-SpeedCalc displays it exactly as you entered it or as it was calculated from a formula.
Width (CTRL-W). The width command changes the width of an entire column of cells. Move the cursor to any cell in the desired column, then press CTRL-W. When SpeedCalc displays the prompt WIDTH:, respond with a number from \(4-36\). The entire screen is redrawn to accommodate the new format, and may look very different depending on what value you chose. For instance, if you increase a column's width, the rightmost column of the former display may disappear: SpeedCalc only displays as many complete columns as it can fit on the screen. If you decrease the width of a column, you may see asterisks where numbers used to be (indicating the cell is now too small to display the entire number). To get rid of the asterisks, expand the column as necessary.
Global Format (OPTION-CTRLF). This is the same as the ordinary format command, but operates globally, changing every cell in the sheet instead of just one.
Global Width (OPTION-CTRLW). This is a global version of the width command. Every column in the sheet changes to the designated width.

\section*{Screen Color And Luminance}

SpeedCalc makes it easy to change the screen background and character colors to your liking.
Background Color (CTRL-B). Press CTRL-B to cycle forward through the available screen background colors.
Text Color (CTRL-T). This command increases the luminance of characters on the screen, cycling forward through all of the available text colors.
Previous Background Color (OPTION-CTRL-B). The reverse of CTRL-B, this command cycles backward through the range of background colors.
Previous Text Color (OPTION-CTRL-T). The reverse of CTRL-T, this command cycles backward through the range of text colors.

\section*{Macro Editing}

After typing in a large spreadsheet, you may decide to make a major change. You may want to add new data somewhere in the middle, delete a section, or move a group of cells from one location to another. SpeedCalc's macro (large-scale) editing commands simplify such operations, affecting an entire block of cells at once. A block is simply a group of cells connected in rectangular fashion. You can define it as a single cell, a row or column, or any rectangular area within the spreadsheet.

There are two ways macro commands work: verbatim or relative. To take a simple example, say that cell AA2 contains the formula \(=A A 1 * 5\) and you want to move its contents to cell AB2. When this is done in verbatim mode, \(A B 2\) contains an exact copy of what was in AA2 (=AA1*5). Note that the cell name used in the formula does not change: The formula still refers to AA1. If you perform the same operation in relative mode, the cell name in the formula is adjusted to fit the new location. In this case, AB2 would contain the formula \(=A B 1 * 5\).
Copy (CTRL-C). The copy command copies a block of cells into a different location without disturbing the original cells. Place the cursor on the upper-left corner of the block you want to copy, then press CTRL-C. SpeedCalc prompts you to move the cursor to the lower-right corner of the block you want to copy. Once the cursor is in place, press RETURN. Now SpeedCalc prompts you to move the cursor to the place where you want to put the block: This is the upper-left corner of the new position. Once the cursor is there, press RETURN again. The new data replaces whatever was contained in the designated cells. Note that if you define an impossible block (for instance, moving the cursor to the upper-left of the original position, rather than below and to the right), SpeedCalc does not copy any data. Press ESC if you change your mind and wish to cancel this command.
Move (CTRL-M). This command works like a copy, but it fills the original cells with blanks. Though

SpeedCalc has no express insert command, you can use this command to make space for new data in the middle of a spreadsheet. Simply move everything below the insertion point down as far as you need. As with the copy command, you can press ESC to cancel this command.
Relative Copy (OPTION-CTRLC). This form of the copy command adjusts the cell names used in formulas within the copied block (see explanation above). When copying or moving data in relative mode, you may see some strange characters displayed very briefly in the input buffer area of the screen: This harmless effect occurs because SpeedCalc uses that area for temporary storage during these operations, conserving memory for other purposes.

\section*{Relative Move (OPTION-CTRL-} M). This is the relative form of the move command. Cell names in formulas are adjusted to reflect the move.

\section*{Memory Management}

SpeedCalc makes about 20K (roughly 20,000 characters) of memory
available for data. As noted earlier, SpeedCalc lets you spread your data out over a much larger number of cells than you can actually fill with data. The extra space is provided to give you full control over the final format of the spreadsheet and to leave some elbow room for move and copy operations.

Because memory is limited, you should keep careful track of how much is free while using the program. Press CTRL-A to display the amount of free memory. We suggest limiting your spreadsheets to 1,600 cells (equivalent to 40 rows by 40 columns). If you've filled nearly all of free memory, you may have to break the spreadsheet into two smaller sheets.

Although SpeedCalc checks the amount of available memory and displays an error message if you run out, you should be careful not to exhaust free memory. Any move or copy operation in process will be aborted if sufficient memory is not available.

\section*{Disk Operations}

SpeedCalc has three disk commands for saving and loading data from

\section*{SpeedCalc Commands}
\begin{tabular}{ll} 
Command & Action \\
CTRL-A & available memory check \\
CTRL-B & next background color \\
CTRL-C & copy block verbatim \\
CTRL-D & disk directory \\
CTRL-E & edit current cell \\
CTRL-F & change cell format \\
CTRL-G & goto selected cell \\
CTRL-H & home cursor \\
cTear current cell \\
CTRL-K & load SpeedCalc file \\
CTRL-M & move block verbatim \\
CTRL-N & recalculate sheet now \\
CTRL-P & print cells from AA1 to cursor \\
CTRL-R & turn recalculation on/off \\
CTRL-S & save SpeedCalc file \\
CTRL-T & increase text luminance \\
CTRL-W & exit Speedlumn width \\
CTRL-X & change decimal to DOS \\
Clear spreadsheet
\end{tabular}
disk and displaying the disk direc－ tory．The disk directory command is the easiest to use：Simply press CTRL－D．To save a spreadsheet to disk，press CTRL－S．SpeedCalc prints SAVE：on the command line， followed by a cursor．Enter a valid Atari filename（including D：）and press RETURN．（If you change your mind and decide not to save any－ thing，press RETURN without typ－ ing a filename．）If no disk error occurs while the spreadsheet is be－ ing saved，SpeedCalc displays NO ERRORS in the command line and returns you to command mode．If there was an error，you＇ll hear a beep and see the message I／O ER－ ROR \＃followed by an error num－ ber in the command line．Your DOS manual explains the meaning of the various DOS errors．

To load a saved file from disk， press CTRL－L．Again，you can can－ cel the operation by pressing RE－ TURN without entering a filename． SpeedCalc prompts you to enter the filename and displays the error sta－ tus when the operation is complete． If an error occurs while loading， SpeedCalc clears the partially load－ ed sheet to prevent a program crash．

\section*{Printing}

SpeedCalc lets you print data to three different devices：to the screen for previewing output（ E ：）， to a printer for permanent docu－ mentation（P：），or to a disk file for integrating the data with a Speed－ Script document（D：filename）．

To print a hardcopy of the spreadsheet to a printer，press CTRL－P and then enter P：when asked for（Device：Filename）．Before using this command，you must posi－ tion the cursor below and to the right of the block of cells you wish to print． The upper－left corner of the print－ out starts at cell AA1．To preview the printed output on the screen， enter E ：in response to the same prompt．

You can also print SpeedCalc data to a disk file for use in a Speed－ Script document．When SpeedCalc prints the prompt（Device：File－ name），enter D：filename．The data is saved as a disk file of that name． Note that printing to disk creates a different type of file than saving to disk，and SpeedCalc cannot reload
files in the print format．You should save files you wish to reload into SpeedCalc，and print files you wish to load into SpeedScript．

\section*{SpeedScript Integration}

SpeedCalc sends data to the printer in simple，plain vanilla form．That may be fine for personal use，but if you＇re creating a document for oth－ ers to view，you may want special features such as boldface，underlin－ ing，italics，and so on．Since Atari SpeedScript－COMPUTE！＇s popular word processor－already offers a way to access these features（and many more），no attempt has been made to duplicate them in SpeedCalc．

No special tricks are needed to load a SpeedCalc file into Speed－ Script．After printing the file to disk as explained above，exit SpeedCalc， then load and run SpeedScript．Now load the file as you would any SpeedScript document．The data ap－ pears on the screen，ready to be edited in any way you wish．Again， keep in mind that SpeedScript can load only those files which have been printed to disk，not saved．

\section*{Program 1：Ałarl SpeedCalc}

Please refer to the＂MLX＂article in this issue before entering the following listing．

\title{
Fractal Graphics
}

\section*{Paul W．Carlson}

One of the hottest topics in mathe－ matics these days is fractals－frac－ tional dimensions．Fractals are being used for everything from simulating random plant growth to generating realistic planetary landscapes for sci－ ence－fiction films and arcade games． This article，adapted from＂Apple Fractals＂in the September 1985 issue of COMPUTE！，introduces the fascinat－ ing world of fractals with three pro－ grams that work on any IBM PCjr or PC with color／graphics adapter．

The term fractal was coined by Be－ noit Mandelbrot，a pioneer in their study，to denote curves or surfaces having fractional dimension．The concept of fractional dimension can be illustrated as follows：A straight curve（a line）is one－dimensional， having only length．However，if the curve is infinitely long and curves about in such a manner as to com－ pletely fill an area of the plane con－ taining it，the curve could be considered two－dimensional．A curve partially filling an area would have a fractional dimension be－ tween one and two．

Many types of fractals are self－ similar，which means that all por－ tions of the fractal resemble each other．Self－similarity occurs when－ ever the whole is an expansion of some basic building block．In the language of fractals，this basic building block is called the genera－ tor．The generator in the accompa－ nying programs consists of a
number of connected line seg－ ments．The curves that the pro－ grams plot are the result of starting with the generator and then repeat－ edly replacing each line segment with the whole generator according to a defined rule．Theoretically， these replacement cycles would continue indefinitely．In practice， the screen resolution limits the number of cycles．

The programs illustrate two types of fractal curves．The curves generated by Program 1 and Pro－ gram 2 are self－contacting，while the curve generated by Program 3 is self－avoiding．A self－contacting curve touches itself but does not cross itself．A self－avoiding curve never actually touches itself al－ though it may appear to because of the limited screen resolution．

\section*{The Dragon Sweep}

Program 1 plots what Mandelbrot refers to as a＂dragon sweep．＂It demonstrates in a step－by－step fashion how a fractal curve is filled．

The generator consists of two line segments of equal length forming a right angle. During each replacement cycle, the generator is substituted for each segment on alternating sides of the segments, that is, to the left of the first segment, to the right of the second segment, and so on. Figure 1 shows the first few cycles of substitution. The program is written in BASIC so the plotting is slow enough to let you observe the development of the curve.

The program prompts you to enter an even number of cycles (for reasons of efficiency and screen resolution, only even numbers of cycles are plotted). When a plot is complete, pressing any key clears the screen and returns you to the prompt. I recommend starting with two cycles, then four, six, etc. It takes fourteen cycles to completely fill in the "dragon," but since this requires almost two hours, you will probably want to quit after about ten cycles. You can see the complete dragon by running Program 2, which always plots the dragon first in less than 30 seconds.

Since it's not at all obvious how the program works, here's a brief explanation. NC is the number of cycles; C is the cycle number; SN is an array of segment numbers indexed by cycle number; L is the segment length; D is the segment direction, numbered clockwise from the positive \(x\) direction; and \(X\) and \(Y\) are the high-resolution screen coordinates.

Lines 100-140 Get number of cycles from user.
Line 150 Computes segment length.
Line 160 Sets starting coordinates.
Line \(170 \quad\) Sets segment numbers for all cycles to the first segment.
Lines 180-220 Find the direction of the segment in the last cycle by rotating the segment in each cycle that will contain the segment in the last cycle.
Lines 230-260 Increase or decrease \(X\) or \(Y\) by the segment length, depending on the segment direction.
Lines 270-290 Plot the segment and update the current segment number for each cycle.
Lines 300-320 If the segment number for cycle zero is still zero, do the next segment; otherwise, we're done.

\section*{Eight Thousand Dragons}

Program 2 plots more than 8,000 different dragons. It does this by randomly determining on which side of the first segment the generator will be substituted for all cycles after the first cycle. The generator is always substituted to the left of the first segment in the first cycle to avoid plotting off the screen. Other than the randomization, this program uses the same logic as Program 1. The main part of this program is written in machine language to reduce the time required to plot a completely filled-in dragon from about two hours to less than half a minute.

All the dragons are plotted after 14 cycles of substitution. All have exactly the same area, which equals half of the square of the distance between the first and last points plotted. All the dragons begin and end at the same points.

When a plot is complete, press the space bar to plot another dragon, or press the Q key to quit.

\section*{Snowflakes}

Program 3 plots what Mandelbrot refers to as a "snowflake sweep." The generator, shown in Figure 2, was discovered by Mandelbrot. The
segments are numbered zero through six, starting at the right. The program is basically the same as Program 1. The variables NC, C, SN, D, \(X\), and \(Y\) represent the same values except that the direction \(D\) is numbered counterclockwise from the negative \(x\) direction. For each segment, the accompanying table gives the value of RD (relative direction), LN (length factor), and SD (flags indicating which side of the segment the generator is to be placed).

\section*{Figure 1: Substitution Cycles,} Program 1

Cycle 1

Cycle 2

Line 20 Reads values of SD and RD. Compute LN values.
Lines 30-50 Compute delta x and delta y factors for each direction.
Lines 60-100 Get number of cycles from user.
Line 120 Sets starting coordinates.
Line 130 Sets the segment numbers for all cycles to the first segment.
Lines 140-170 Find the direction of the segment in the last cycle.

Lines 180－190 Compute the coordinates of the end of the segment， plot the segment，and up－ date the segment numbers for each cycle．
Lines 200－220 Same as lines 300－320 in Program 1.
Like Program 1，pressing any key when a plot is complete clears the screen and brings another prompt．

\section*{Experiment}

I hope these programs encourage you to look further into the fasci－ nating world of fractals．Don＇t be afraid to experiment with the pro－ grams－try modifying the shape of the generator in Program 3，for ex－ ample．Better yet，design your own generator．

These programs just begin to explore the possibilities of fractal computer graphics．There is anoth－ er whole class of fractals，those gen－ erated by functions of complex variables．And then there are three－ dimensional fractals．And then．．．

\title{
Commodore ML Saver
}

\author{
Buck Childress
}

This short, useful program saves any machine language program directly from memory into a disk or tape file. It works on any Commodore 64 or 128 (in 64 mode).

There are many useful machine language (ML) utilities available in public domain collections, on computer bulletin boards, and in publications like COMPUTE!. The most common way to place an ML program in memory is with a BASIC loader-a BASIC routine which READs the necessary values from DATA statements and POKEs them into memory. That method is fine for short ML programs, but can involve quite a delay when the ML program is long. It takes time, first of all, to load the BASIC loader. Then there's another wait while it POKEs everything into memory.

A much faster technique is to load the ML from disk or tape directly into memory. The only problem is making the tape or disk file. Machine language monitors such as Supermon can save any ML program directly from memory. But if you don't have a monitor, or don't know how to use one, that's not a viable option, either.

\section*{A Better Way}
"ML Saver" is a short BASIC utility that can save any machine language program on disk or tape directly from where it resides in memory. After you type in and save ML Saver, load and run the program that creates the ML code you want to save. Make a note of the
starting and ending addresses. If the ML is POKEd into memory with a FOR-NEXT loop, these addresses usually appear in the loop itself. For instance, if the loop is FOR J=49152 to 51000:READ Q:POKE J,Q:NEXT then you know the starting address is 49152 and the ending address is 51000. Now check the SYS address used to activate the program. This is usually the same as the starting address (for example, SYS 49152), but some programs are activated by jumping to an address somewhere in the middle of the code.

Once you have this information, you're ready to load and run ML Saver. The program asks you for the name you want to save the ML program under: Enter any name up to eight characters in length (extra characters are ignored). After you've supplied the name, enter D to save to disk or T for tape. Then enter the starting and ending addresses you wrote down earlier. ML Saver proceeds to save the ML code.

After the file has been created, you can load it with LOAD"filename", 8,1 for disk or LOAD"filename" \(, 1,1\) for tape (of course, you should replace filename with the filename you used when saving the program). Then SYS to the correct address to activate the program. To do this under program control, put the following statements at the beginning of your program:

\section*{10 IF J=1 THEN 30}
\(20 \mathrm{~J}=1: \mathrm{LOAD}\) "filename", 8,1
30 REM PROGRAM CONTINUES HERE
When you run a program containing these lines, the variable J
equals 0 , so the computer falls through the IF test in line 10 and performs line 20. This line sets \(J\) to a nonzero value and loads the ML. After the load is complete, the computer automatically reruns the program beginning at line 10 , but does not erase previously established variables. This time around, J equals 1 , so the computer skips line 20 and proceeds with line 10 . ©

\section*{Commodore ML Saver}

\title{
Loading And Linking Commodore Programs Part 1
}

\author{
Jim Butterfield, Associate Editor
}

This series covers the ins and outs of loading, chaining, and overlaying programs on Commodore computers.

The LOAD command seems easy enough to understand: It brings a program into memory from disk or tape. But it has special features and pitfalls. And when you cause one program to load another program, you enter the special field of chaining, overlaying, and bootstrapping. Let's take a close look at all of these operations, beginning with the LOAD command.

LOAD performs some subtle tasks, including relocating a program if necessary and a delicatep job called relinking. There are special rules that apply when you load a program that was saved on a different type of Commodore computer. In fact, it sometimes works better to forget about LOAD and use a different technique. And the LOAD command behaves differently when executed by a program than it does when you enter it directly from the keyboard.

Most of the principles we'll cover in this series apply to programs stored on both disk and tape. It's easier to give examples that apply to disk systems, mostly because of the simplicity of setting up demonstration files. But you can still learn a lot about LOAD even if you don't have a disk drive.

\section*{What LOAD Does}

When a LOAD command is executed, the following things happen:
- A PRG (PRoGram-format) file is brought into memory. Program is just the name for a certain type of file. The material contained in the file doesn't need to be a program. It could be a block of data, a screen, a character set, or anything.
- If the LOAD command doesn't specify nonrelocation, the information is normally relocated. That is, no matter what memory location it was saved from, it's loaded into memory beginning at the start of BASIC program space. PET/CBM computers are an exception to this rule: They never relocate programs. There's also a special cassette format available on VIC-20 and Commodore 64 computers which forces nonrelocation. (Unfortunately, this format is not easy for the beginner to create.)
- If the LOAD command specifies nonrelocation, the information is placed in memory at the same addresses from which it was saved. This is generally done by adding , 1 at the end of the LOAD command. For example, LOAD "PROG", 8 loads the file PROG from disk and relocates it in memory, but LOAD"PROG", 8,1 loads without relocating.
- If there were no errors during the load, the reserved variable ST is set to 0 (for tape) or 64 (for disk). It's often a good idea to check ST after loading. You can't rely on BASIC to catch every conceivable load error, particularly with tape. If you're using a disk drive, it's a good idea to check the drive status or at least see
if the red error light is flashing.
- After the load is complete, the program is relinked (more about relinking in a moment).
- If the LOAD command was issued in direct mode (from the keyboard), all variables are cleared and the BASIC start-of-variables pointer is set to the first byte past the last byte that was loaded.
- If the LOAD command was issued by a program, variables are not cleared and the program automatically reruns from the beginning. This creates powerful opportunities, but requires some special handling to work correctly.

After a load is finished, what ends up in the computer's memory isn't quite the same as what you originally typed on the keyboard. For one thing, keywords are token-ized-compressed into single-byte values. When you type in the letters P-R-I-N-T, the BASIC word PRINT is "crunched" together into a single byte which the computer recognizes as PRINT. And the picture is further complicated because different Commodore computers use slightly different tokenizing schemes (we'll return to this point a bit later).

\section*{Relinking}

When a BASIC program is in memory, each program line is linked to the next line by a chain of pointers (often called line links). At the start of each line there's a two-byte pointer that shows where the next line starts. The end of the program
is marked by a pointer that consists of two zeros.

What's the purpose of the chain? When the computer runs a program, there are many times when it needs to find a line number quickly-to execute a GOTO or GOSUB, for example. Rather than wade through every character of every line, it can skip from one link to the next until it finds the line it needs.

Each two-byte pointer shows the actual memory address where the next line begins, and these links are saved with the program. After a relocating load, which may bring the program into a different memory area, the pointers may point to the wrong locations. To fix everything up, the computer automatically relinks every line in the program after loading it into memory.

Relinking is a simple job. The computer scans through each program line, looking for the zero byte that marks the end of that line. As soon as it finds this address, the computer knows where the next line begins-at the next byte past the first line's end. It then rewrites the link for the first line and leaps ahead to repeat the process.

\section*{Relinking Problems}

Two things can go wrong during the relinking process. If you load a chunk of data that doesn't contain any zero bytes, the computer can't find any end-of-line markers and won't be able to relink at all. The second difficulty is fortunately quite obscure: There's a model of computer called the B system in North America and the 700 series in Europe. The most well-known model in the USA is the B128 (not to be confused with the Commodore 128), but the comments here apply to all B and 700 models. When you save a BASIC program from these computers, the program is stored in an unusually low memory address. Because the saved program contains zeros in unexpected places, other Commodore computers can't make any sense of the chain.

Let's create an unlinkable file. If you have a disk drive, enter the following statements in direct mode (without line numbers), pressing RETURN after each line:

OPEN 8,8,8,"0:CRASHER,P,W" PRINT\#8,CHR\$(1);CHR\$(4); FOR \(\mathrm{J}=1\) TO
300:PRINT\#8,CHR\$(4);:NEXT
CLOSE 8
Don't forget to put a semicolon at the end of each of the two PRINT\# statements.

IF you LOAD "CRASHER", 8 the computer prints LOADING and READY, but the cursor doesn't return. It's stuck in an endless loop, looking for the nonexistent zero that marks the end of the first BASIC line. This kind of crash is fairly common on cassette systems, when a bad load fills memory with garbage. It can also occur with disk if you forget to add , 1 to a LOAD command that requires relocation, loading something odd like a screen image into the BASIC program area. You can usually recover control by pressing RUN/STOP-RESTORE and entering NEW.

Before we look at a solution to the second problem, let's talk about another area where incompatibility arises between machines.

\section*{LOAD Address Incompatibility}

PET/CBM computers can't relocate programs at all. On a PET/CBM, BASIC program space starts at location 1025. Most other Commodore computers use a different address, meaning that the PET/CBM can't load programs saved on those computers. The program following this article is a converter to solve both of these problems. You'll need a disk drive to use it.

The new file created by the program is loadable by any eightbit Commodore computer. Since it sets the load address to 1025, PET/CBM computers can load it properly (all other models relocate it automatically). To make B128 program files usable by other computers, it puts dummy link bytes (both containing a 1 ) at the beginning of each line. Remember, all these computers relink programs automatically, so this problem can be solved by putting any nonzero values in the links.

This program works only with BASIC programs, since it stops at the two zero bytes that mark the end of the program. If there's something more "pasted" onto the end of the BASIC text-a machine lan-
guage routine, for example-it will not be copied.

\section*{Alternative Method}

If you have access to the type of computer which generated the original program, there's an easier way to do the same thing. You can make a Commodore 64 emulate the memory configuration of another machine so BASIC programs are kept in a more compatible part of memory. If you move the start of BASIC to location 1025, the links will be more conventional and the program will be PET-compatible.

To make the area at 1025 available for BASIC, we'll also need to relocate the screen to a new area. To fit the following commands onto two screen lines, you can abbreviate PRINT as ? and POKE as P SHIFT-O:

\section*{POKE56576,5:POKE 53272,4:POKE648,128 :POKE1024,0:POKE44,4:POKE56,128 :PRINTCHR\$(147):NEW}

The first three POKEs move the screen. The next three move the start and end of the BASIC area, and the last two commands clear the new screen and set up the new BASIC work area.

Once you've entered the above commands, your Commodore 64 emulates a PET/CBM's BASIC configuration. You may now convert a BASIC program into compatible format by loading it into the reconfigured machine and saving it again. By using this load/save sequence, you're making several things happen. When you load the program, it's relocated into a new area. The chain links are then rebuilt to be compatible with the new memory space. When you save, the newly relocated program-complete with new links-is placed on disk or tape.

The modified program seems the same, but it now has a "universal" style. Whether you created it with the Converter program below or with the POKEs and LOAD/ SAVE sequence, it can now be loaded into any eight-bit Commodore machine. Its addresses are directly compatible with the PET/CBM, and other machines will relocate the program as it loads. And we've eliminated the possibility of the peculiar B128 chain that confuses other Commodore computers.

\section*{Incompatible Tokens}

Some programs won't transfer from one machine to another because of differences in the BASIC tokens. You'll have little trouble with commonly used commands such as PRINT and IF. The difference comes with more advanced commands that aren't part of every version of Commodore BASIC. If you write a program in CBM BASIC 4.0 and use commands like DLOAD and SCRATCH, don't be surprised to find that it doesn't run properly on a Commodore 64. Those commands don't exist in the 64's BASIC.

You might also be surprised to find that a Plus, 4 or Commodore 128 (in 128 mode) can't run the PET/CBM program either, even though both of those machines have DLOAD and SCRATCH commands. Why not? The commands are there, but they're represented by different token values.

In such cases, you can't use LOAD and SAVE at all. What you'll
have to do is detokenize the program by LISTing it to a disk file, then bring it back into memory with a "merge" method like the one described in "Commodore Dynamic Keyboard, Part 3" (COMPUTE!, December 1985).

We've only scratched the surface of the many uses of the LOAD command. When we start to look into chaining, overlaying, and reloading techniques, we'll discover that the LOAD command has amazing potential.

\title{
Atari P/M Graphics Toolkit
}

\author{
Tom R. Halfhill, Editor
}

If you're mystified by Atari player/ missile graphics, this article is for you. With help from a toolkit of routines written in BASIC and machine language, you'll soon be writing your own programs that move shapes of your own design anywhere on the screen quickly and easily. For all 400/800, XL, and XE computers with Atari BASIC.

It's safe to say that no feature on Atari computers is as exciting and as frustrating as player/missile graphics.

Exciting: \(\mathrm{P} / \mathrm{M}\) graphics provides four larger objects called players and four smaller objects called missiles which can be displayed in almost any shape or color and animated on the screen. You can even achieve 3-D effects by making the objects pass above and beneath background graphics and each other.

Frustrating: Atari BASIC has no special commands for using \(\mathrm{P} / \mathrm{M}\) graphics, standard Atari manuals don't cover P/M graphics, you can't set up \(\mathrm{P} / \mathrm{M}\) graphics in a program without worrying about lots of POKEs and protecting memory, and Atari BASIC lacks a straightforward way to move a \(\mathrm{P} / \mathrm{M}\) object vertically or diagonally at speeds faster than a crawl. Furthermore, there's no easy method of designing player shapes without scribbling on graph paper and adding up binary bit values of bytes.
"Atari P/M Graphics Toolkit" solves all these problems and more. It's a package of routines written in BASIC and machine language that can form the core of your own programs. With the Toolkit, you can easily design your own shapes with
a joystick, then write simple BASIC programs that automatically set up \(\mathrm{P} / \mathrm{M}\) graphics and instantly move your objects anywhere on the screen.

You've probably used or heard of similar programs in other magazines and books. In fact, several popular routines for animating \(\mathrm{P} / \mathrm{M}\) graphics appeared in early issues of COMPUTE! and are reprinted in various COMPUTE! books. But the P/M Graphics Toolkit offers these advantages:

\section*{Special Features}
- The Toolkit setup/animation routine creates a true \(X-Y\) coordinate system for moving \(\mathrm{P} / \mathrm{M}\) objects to any horizontal-vertical position on the screen. This system is patterned after the \(\mathrm{X}-\mathrm{Y}\) coordinates in Atari BASIC graphics modes, so if you know how to use the PLOT, DRAWTO, LOCATE, or POSITION commands, you should have no trouble animating \(\mathrm{P} / \mathrm{M}\) objects with the Toolkit.
- A machine language subroutine automatically clears out the P/M memory area in a flash, so your programs initialize faster.
- The Toolkit routines work in single-resolution or double-resolution P/M graphics modes, and in any screen graphics mode.
- Unlike most other programs of this type, the Toolkit lets you move any of the four missile objects as easily as any of the four players.
- The Toolkit allows you to instantly change the shape or size of a \(\mathrm{P} / \mathrm{M}\) object by selecting from any number of previously designed shapes-even while the object is moving.
- Because all of its machine language is written to be completely relocatable, you can add the Toolkit
setup/animation routine to any BASIC program without fear of memory conflicts with other ML routines you may be using.
- Best of all, using the Toolkit is a snap. Once the Toolkit setup/animation routine is added to your program, initializing \(\mathrm{P} / \mathrm{M}\) graphics requires only one line of BASIC, and all of the animation and shapeflipping can be done with just a single BASIC statement.

\section*{Getting Started}

All of these features are contained in the setup/animation routine listed below as Program 1. This will be the basic building block of your own programs, so the line numbers start at 20000 to leave plenty of room for your own lines.

Be sure to type in Program 1 using COMPUTE!'s "Automatic Proofreader" utility, because the DATA statements in lines 2017020593 are extremely critical-they encode the machine language for two ML subroutines. When you're done, store Program 1 on disk or tape with the LIST command, not SAVE or CSAVE:
LIST"D:filename.ext" for disk
LIST"C:" for cassette
This way, you can use the ENTER command (ENTER"D:filename.ext" or ENTER"C:") to merge the routine with another program already in memory, as we'll demonstrate in a moment.

\section*{A Single-Line Sełup}

To create a program that uses player/missile graphics, you only have to call this routine once. The call should be as near to the beginning of your program as possible; the first line is ideal. Here's the proper format:
10 GRMODE \(=0:\) PMMODE \(=1:\) GOSUB
20050

Set the variable GRMODE to whatever graphics mode you desire. Any valid number or expression you'd use with the GRAPHICS statement will work. In the above example, we're asking the Toolkit routine to set up GRAPHICS 0 . Set the variable PMMODE to the player/missile graphics mode you want: either 1 for single-line resolution or 2 for double-line resolution. (If you aren't familiar with \(\mathrm{P} / \mathrm{M}\) modes, see "Atari Animation with P/M Graphics," a three-part series beginning in the September 1985 issue of COMPUTE!. Even though the Toolkit routines automatically perform the memory allocation and animation chores discussed in this series, I strongly recommend acquiring some background on \(\mathrm{P} / \mathrm{M}\) graphics.)

The third statement in the sample line above actually calls the Toolkit setup/animation routine. Notice that it GOSUBs to line 20050 instead of 20000. Lines 20000-20040 are REM statements, and it's good programming practice to avoid a GOSUB or GOTO reference to a REM because some people delete REM statements from programs to save memory.

When you call the routine in this manner, there will be a pause of several seconds as it loads the machine language into memory. Then, in rapid sequence, the routine automatically protects the right amount of memory for the \(\mathrm{P} / \mathrm{M}\) mode you requested; instantly clears out any old data in that memory area; performs all the POKEs necessary to set up P/M graphics; assigns colors to all four players and missiles; and switches to the graphics mode you requested. In other words, it does all of the dirty work for you.

When the Toolkit routine is finished, a RETURN statement passes control back to whatever line follows the GOSUB. That's where the rest of your program should continue. Be sure to place an END statement at the end of your own program lines, but before line 20000, so the Toolkit routine doesn't accidentally execute more than once.

If you want to change the player colors from the colors assigned
by the Toolkit routine, POKE your own color values into locations 704-707.

\section*{PMMOVE Magic}

After this simple setup, all it takes is one BASIC statement to move any player or missile anywhere on the screen. Here's the format:

\section*{A = USR(PMMOVE,PLAYER\#,SHAPE ,SIZE,X,Y)}

Let's take a look at these parameters one at a time. We'll follow with a few examples.

The variable \(A\) is a dummy variable required by the USR state-ment-with this routine, it returns no useful value. PMMOVE is the address of the machine language subroutine, and its value is automatically set when your program executes the GOSUB 20050 described above. (PMMOVE is actually the address of PMMOVE\$, a string which holds the ML data.) Don't change the value of PMMOVE unless you enjoy watch-
ing your computer crash.
The remaining five parameters are under your control. You must assign values to these parameters yourself and always include them when calling the PMMOVE routine.

PLAYER\# should be a number from 1 to 8 that specifies which \(\mathrm{P} / \mathrm{M}\) object will be affected by the statement. Numbers 1 to 4 specify the four players, and numbers 5 to 8 specify the four missiles.

SHAPE is the address of the shape data for the player or missile. The best way to use this parameter is to specify the address of a string which contains previously created shape data. For background on designing player shapes, see Part 2 of the three-part series mentioned above. In a moment, we'll discuss a Toolkit utility that lets you design your own shapes with a joystick and which calculates the shape data for you. The SHAPE parameter, incidentally, is what allows players to flip between different shapes even

\section*{PMMOVE SCREEN COORDINATES}

\section*{SINGLE RESOLUTION}

DOUBLE RESOLUTION

while they're moving. Each time you move a player or missile, the PMMOVE subroutine erases the object's entire memory area and replaces it with the new image you select with the SHAPE parameter. If you don't quite follow this explanation, the example programs will clarify things.

SIZE is the height of the player or missile in bytes. If the shape data referred to by SHAPE consists of eight bytes, you'd insert an 8 for this parameter. This makes it possible to store the data for numerous player shapes in a single string, then select just the shape you want by pointing SHAPE to its position within the string and specifying the substring's length with SIZE. Again, the example programs will demonstrate this technique.

The final two parameters determine the new position of the player or missile on the screen. \(X\) is the horizontal coordinate and \(Y\) is the vertical coordinate. Like the screen coordinates used by BASIC graphics commands such as PLOT and DRAWTO, position 0,0 refers to the upper-left corner. As the X coordinate increases, the \(\mathrm{P} / \mathrm{M}\) object moves from left to right; as the \(Y\) coordinate increases, the object moves from top to bottom. \(X\) values can range from 0 to 255 . Y values can range from 0 to 255 in singleresolution \(\mathrm{P} / \mathrm{M}\) graphics or 0 to 128 in double-resolution \(\mathrm{P} / \mathrm{M}\) graphics. If the \(X\) or \(Y\) values exceed these ranges, the object eventually "wraps around" to the opposite side of the screen. But if you specify an \(X\) or \(Y\) value which is less than 0 , an error results.

The accompanying figure shows the layout of these coordinates. Notice how some positions are off the visible screen area. A quick way to make an object disappear is to move it to one of these "invisible" positions. (Another way is to specify 0 for the SIZE parameter.)

\section*{Frame Flipping}

Now for the fun stuff. The following examples show some typical ways to use the PMMOVE statement in your own programs.

Program 2 demonstrates how to store a player shape in a string. After typing Program 2, LIST it to
disk or tape, then merge it in memory with Program 1 by using the ENTER command. When you type RUN, there's a pause as everything sets up, then a player in the form of a smiling face appears in the center of the screen. Here's how it works:

Line 10 calls the Toolkit setup routine (Program 1), specifying sin-gle-resolution \(P / M\) and graphics mode 0 . Line 20 dimensions the string variable SHAPE\$ to hold 11 characters, the size of the player (11 bytes tall). Next it uses BASIC's ADR function to set the variable SHAPE to the address of SHAPE\$, and sets SIZE to 11. Then it uses a FOR-NEXT loop to read the 11 bytes of shape data in line 40 into SHAPE\$.

Finally, the PMMOVE statement in line 30 makes the player appear at position 127,127 (the centerpoint in single-res P/M graphics). Note that the PLAYER\# parameter is 1 ; simply by changing this number to 2,3 , or 4 , you can display any of the other players using the same shape data-try it. (By the way, you should press SYSTEM RESET before rerunning this or any other program that uses player/missile graphics. Otherwise, the reserved \(\mathrm{P} / \mathrm{M}\) memory keeps growing until it consumes all the RAM in your computer.)

The technique of storing player shape data in strings has some interesting applications. By storing several shapes in a single string and flipping rapidly between them, you can make your players come alive as they move about the screen. Even a static player can seem to move as its shape continuously changes, much like frame animation in a cartoon. To see an example, type in Program 3. LIST it to disk or tape, then merge it in memory with Program 1 using the ENTER command. When you type RUN, the program initializes for a few seconds, then displays a small explosion in the middle of the screen, hurling fragments in all directions. Yet, throughout this animated sequence, the player object never moves.

The secret is BOOM\$, a 64character string filled with eight player shapes in line 30 . Each shape is eight characters long, as seen in the DATA statements in lines

90-160. The PMMOVE statement in line 60 rapidly flips through all eight shapes in sequence because it is sandwiched within the FORNEXT loop between lines 40 and 80. (The loop serves double duty; it also fades the explosion sound into silence.) Another FOR-NEXT in line 70 is a simple delay loop. To slow down the explosion sequence for a better idea of what's going on, change the 35 in line 70 to a larger number-say, 150. Also notice how the final player shape in this sequence consists of nothing but zeroes. This is another way of making the player object seem to disappear without moving it off the screen.

\section*{Whirling Dervishes}

Another fascinating application of this technique is to design players which change shape depending on which direction they're moving. To see an example, type in Program 4. As before, LIST the program to disk or tape, then merge it with Program 1 using ENTER.

When you type RUN, a red tank appears in the center of the screen. The low rumble of an idling engine can be heard in the background. Plug a joystick into port 1, then try moving the stick right or left. Notice how the tank rotates clockwise or counterclockwise. In fact, it spins so fast it's almost a blur.

The player isn't actually rotating or moving, of course; it's simply changing shape many times per second, thanks to the SHAPE parameter of the PMMOVE routine. The secret, again, is a string (SHAPE\$) which contains shape data for eight tank images, one for each of the eight possible directions. Lines \(40-80\) read the joystick and determine which image should be displayed.

Now push the joystick forward. The engine revs up and the tank obediently moves in the direction it is pointed. You can drive the tank all over the screen. To see how this works, study lines \(90-190\). Notice how the ON-GOTO statement in line 90 passes control to one of the lines from 120 to 190, depending on which direction the tank is oriented. Each of these lines either increments or decrements the \(X\) and

Y coordinates to move the tank in one of the eight possible directions.

Notice, too, how this entire program contains only the one PMMOVE statement in line 80-a single statement controls both the player's shape and its movement.

\section*{Stepping On The Gas}

To make the tank move twice as fast, change lines \(120-190\) so the \(X\) and \(Y\) coordinates are incremented or decremented by 2 instead of 1 . For still more speed, you can even change these values to 3 . However, keep in mind that the movement is not quite as smooth as these step values are increased; the object seems to jerk along at higher speeds. A step value of 2 or 3 is a reasonable compromise between speed and loss of grace.

Try changing the PLAYER\# parameter in the PMMOVE statement to 2,3 , or 4 to see the other players in action.

For an example of missile animation, merge Program 5 with both Program 1 and Program 4. These lines let the tank fire a shot when you press the joystick button. The direction routine is very similar to the one in Program 4; in fact, it uses the same variable (DIR) to figure out which way the tank is pointing.

Note how the missile shape defined in line 25 is only one byte long-CHR\$(3). Unlike player objects, which are eight bits wide, missiles are only two bits wide. You can't design a very fancy shape with only two bits to work with, so most programs use the missiles for such tiny shapes as projectiles, bullets, etc. A single byte is enough to define a missile shape for these purposes. Since all four missiles share the same memory area as a single player, defining missile shapes is a little different than defining player shapes.

Rather than getting into a confusing discussion about missiles and bit manipulation, just remember this: The shape bytes for the four missiles (accessed as PLAYER\# \(5,6,7\), and 8 in the PMMOVE statement) should be \(3,12,48\), and 192, respectively. For instance, the PMMOVE statements in lines 1100 and 1110 refer to the first missile, PLAYER\# 5, so its shape data in MISSILE\$ is a 3 . If you want to
move the second missile, change the PLAYER\# parameter to 6 and the shape byte in line 25 to CHR\$(12). If you want to move the third missile, change the PLAYER\# parameter to 7 and the shape byte to CHR\$(48). And if you want to move the fourth missile, change the PLAYER\# parameter to 8 and the shape byte to CHR\$(192). These shape bytes will work with missiles in any of your own programs.

\section*{Designing Player Shapes}

As a final touch, the P/M Graphics Toolkit includes a small utility for designing your own players. It's not very elaborate, but it's better than scribbling on graph paper and counting up "on" bits and "off" bits in your head.

Like the other example programs, the shape utility is based on the Toolkit setup/animation routine. To prepare it, type in Program 6 and merge it with Program 1. SAVE or CSAVE a copy of the merged program so you won't have to repeat these steps each time you want to use the utility.

After typing RUN, select sin-gle- or double-resolution player/ missile graphics by pressing 1 or 2 . The utility spends a few moments initializing, then displays a grid of dots along the left side of the screen. A cursor is at the upper-left corner; it's controlled by a joystick plugged into port 1.

The grid represents a magnified view of an eight-bit-wide player strip, with one dot for each bit. Each horizontal row of eight dots, therefore, represents one byte of the player strip. Player strips are really 255 bytes tall in single resolution or 128 bytes tall in double resolution, but there isn't room to display a grid that large on the screen. Still, the grid is tall enough to design player shapes for most purposes.

To design a shape, just move the cursor anywhere on the grid and press the joystick button to set a bit. The dot changes to inverse video, and an actual-size player begins taking form in the blank area on the right side of the screen. Simultaneously, a number representing the byte value for that row of bits appears. Try moving the cursor and setting more bits; the byte val-
ues keep changing. To erase a bit that you've set, position the cursor on it and press the joystick button again. With each change, the byte values are updated along with the actual-size player.

When you're satisfied with a player shape, jot down the byte values. (You can ignore the zeroes, if any, above and below the shape.) These byte values represent the shape data for your player. To display the player in your own programs, just read the numbers into a string as demonstrated in Programs 2,3 , and 4 . Use the address of this string as the SHAPE parameter in the PMMOVE statement. The number of shape bytes becomes the value for the SIZE parameter.

If you mess things up too badly when designing a player, you can erase the entire grid by pressing the E key.

This is a bare-bones utility, but it's enough to get you started and take the bothersome paperwork out of defining player shapes. If you want, you can add more features of your own-commands to change player colors; to shift bit patterns left, right, up, or down; to flip the pattern as a mirror image; to automatically generate DATA statements of player shape bytes; and so on.

\section*{A Bonus Routine}

Both machine language subroutines used by the Toolkit are designed to be as crashproof as possible. If you accidentally pass the wrong number of parameters in a USR statement, the routines immediately clear all faulty values off the 6502 stack and bounce back to BASIC. So if you call the PMMOVE routine and nothing happens, check the USR statement to make sure you included all of the parameters and that the parameters have legal values.

You may find one of the Toolkit machine language routines useful in other types of programs as well. PAGCLR is a general-purpose routine that rapidly clears a specified number of memory pages with zeroes. For \(\mathrm{P} / \mathrm{M}\) graphics, this routine erases any garbage data that may be cluttering the reserved memory area. But it's handy for any program that needs to clear out a
large amount of memory in a split－ second．

The ML data for PAGCLR can be found in the DATA statements in Program 1 at lines 20160－20240． Line 20060 reads this data into the string PAGCLR\＄，previously DI－ Mensioned to 48 characters．The variable PAGCLR is set to the ad－ dress of PAGCLR\＄．

Here＇s the format for calling the PAGCLR routine：

\section*{A＝USR（PAGCLR，ADDRESS，PAGES）}
where PAGCLR is the address of the ML routine，ADDRESS is the starting address（in decimal）of the memory area you want to clear，and PAGES is the number of memory pages to clear（a page equals 256 bytes）．For example，the last state－ ment in line 20130 clears either 1,024 or 2,048 bytes starting at the memory address PMBASE，de－ pending on whether the variable PAGES is set to 4 or 8 for double－or single－resolution \(\mathrm{P} / \mathrm{M}\) graphics．

Caution：Don＇t use the PAGCLR routine for other pur－ poses unless you understand exact－ ly how it works．If misdirected，it can wipe out massive amounts of memory in an instant and crash your computer．

For instructions on entering these listings， please refer to＂COMPUTE！＇s Guide to Typing In Programs＂published in this issue of COMPUTEI．

\title{
The New Automatic Proofreader For Commodore
}

\author{
Philip I. Nelson, Assistant Editor
}

Now it's easier than ever to type in Commodore programs published in cOMPUTE!. This completely new version of the Automatic Proofreader is a significant improvement over the old Proofreader and catches almost any typing mistake that can be made. A single version now works on the Commodore 64, 128, VIC-20, Plus/4, and 16. Starting with this issue, all BASIC programs published in COMPUTE! for these computers are listed in the new Proofreader format. They cannot be checked with the old Proofreader.
"The New Automatic Proofreader" is a short error-checking program that helps you type in COMPUTE! program listings without typing mistakes. The Proofreader conceals itself in memory and doesn't interfere with the program you're typing. Each time you press RETURN to enter a program line, the Proofreader displays a two-character value called a checksum in reverse video at the top of your screen. If you've typed the line correctly, the checksum on the screen matches the one in the printed listing-it's that simple. You don't have to use the Automatic Proofreader to enter COMPUTE!'s printed listings, but doing so greatly reduces your chances of making a typo.

\section*{Getting Started}

First, type in the Automatic Proofreader program below exactly as it appears in the listing. Since the Proofreader can't check itself before it exists, type carefully to avoid mistakes. Don't omit any lines, even if they contain unfamiliar commands or you think they don't apply to your computer.

When you're finished, save at least two copies on disk or tape before running it for the first time. This is very important because the Proofreader erases the BASIC portion of itself when it runs, leaving only the machine language (ML) portion in memory.

When that's done, type RUN and press RETURN. After announcing which computer it's running on, the Proofreader installs the ML routine in memory, displays the message PROOFREADER ACTIVE, erases the BASIC portion of itself, and ends. If you type LIST and press RETURN, you'll see that no BASIC program remains in memory. The computer is ready for you to type in a new program listing.

\section*{Entering Programs}

Once the Proofreader is active, you can begin typing in a BASIC program as usual. Every time you finish typing a line and press RETURN, the Proofreader displays the two-letter checksum in the up-per-left corner of the screen. Compare this checksum with the twoletter checksum printed next to the corresponding line in the COMPUTE! program listing. If the letters match, you can be pretty certain the line is typed correctly. Otherwise, check for a mistake and correct the line.

The Proofreader ignores space characters that aren't enclosed in quotation marks, so you can omit spaces (or add extra ones) between keywords and still see a matching checksum. For example, these two lines generate the same checksum:

\section*{10 PRINT"THIS IS BASIC"}

10 PRINT "THIS IS BASIC"
However, since spaces inside quotation marks are generally sig-
nificant, the Proofreader pays attention to them. For instance, these two lines generate different checksums:

10 PRINT"THIS IS BASIC" 10 PRINT"THIS ISBA SIC"

A common typing mistake is transposition-typing two successive characters in the wrong order, like PIRNT instead of PRINT or 64378 instead of 64738 . The old Commodore Proofreader couldn't detect transposition errors. Because the new Proofreader computes the checksum with a more sophisticated formula, it is sensitive to the position of each character within the line and thus catches transposition errors.

The Proofreader does not accept keyword abbreviations (for example, typing ? instead of PRINT). If you prefer to use abbreviations, you can still check the line with the Proofreader: Simply LIST the line after typing it, move the cursor back onto the line, and press RETURN. LISTing the line substitutes the full keyword for the abbreviation and allows the Proofreader to work properly. The same technique works for rechecking a program you've already typed in: Reload the program, LIST several lines on the screen, and press RETURN over them.

If you are using the Proofreader on the Commodore Plus/4, 16, or 128 (in 128 mode), do not perform any GRAPHIC commands while the Proofreader is active. When you perform a command like GRAPHIC 1 , the computer moves everything at the start of BASIC program spaceincluding the Proofreader-to another memory area, causing the Proofreader to crash. The same
thing happens if you run any program that contains a GRAPHIC command. The Proofreader deallocates any graphic areas before installing itself in memory, but you are responsible for seeing that the computer remains in this configuration.

Though the Proofreader doesn't interfere with other BASIC operations, it's always a good idea to disable it before running any other program. Some programs may need the space occupied by the Proofreader's ML routine, or may create other memory conflicts. However, the Proofreader is purposely made difficult to dislodge: It's not affected by tape or disk operations, or by pressing RUN/ STOP-RESTORE. The simplest way to disable it is to turn the computer off, then on again.

A gentler method to disable the Proofreader is to SYS to the computer's built-in reset routine. Here are the SYS statements required for various Commodore computers:
\begin{tabular}{ll} 
Computer & Reset Command \\
64 & SYS 64738 \\
128 & SYS 65341 \\
VIC-20 & SYS 64802 \\
Plus/4 & SYS 65526 \\
16 & SYS 65526
\end{tabular}

\section*{Inside The Commodore Proofreader}

Writing a machine language program that works on five different computers is no small task. The first hurdle is finding a safe place to put the code. Though the cassette buffer is an obvious choice, it's located in different places on various machines, and putting ML there creates problems for tape users. Instead, the Proofreader uses 256 bytes of BASIC programming space.

Before it installs the routine in memory, the Proofreader checks which computer you're using. Then it stores the ML at the bottom of BASIC memory and protects itself by moving the computer's start-ofBASIC pointer to a spot 256 bytes higher in memory. Once that's done, the Proofreader activates the ML routine and erases itself with NEW. Note that because the Proofreader overwrites its first few BASIC lines, it's critical not to de-
lete anything from the first portion of the program.

The ML portion of the Proofreader wedges into one of the operating system's built-in routines (CRUNCH). The system calls CRUNCH every time you enter a line from the keyboard (it can be a numbered program line or a direct command without a line number). Before the computer digests the line, it uses CRUNCH to convert BASIC keywords like PRINT into tokens-one- or two-byte numbers that represent the keyword. By changing the CRUNCH vector to point to the ML checksum routine, we can make the computer figure the checksum before it tokenizes the line with CRUNCH.

The checksum routine initially sets the checksum to equal the lowbyte and high-byte values of the current line number. Then it scans the line, multiplying the ASCII value of each character by its position in the line and adding the result to the two-byte checksum as it moves down the line. After scanning the whole line, the Proofreader performs an exclusive or operation on the two bytes of the checksum and displays the final result as two alphabetic characters in reverse video. Though the final checksum could have been displayed as a two-digit hexadecimal number, the Proofreader uses letters so that no harm will be done if you accidentally press RETURN over the line containing the checksum.

Once this is done, the Proofreader restores everything to normal and jumps to CRUNCH, which handles the line as usual.

\section*{Commodore Compatibility}

If you own a Commodore 64, you may already have wondered whether the Proofreader works with other programming utilities. The answer is generally yes, if you are using a 64 and if you activate the Proofreader after installing the other utility. There's no way to promise, of course, that the Proofreader will work with any and every combination of utilities you might want to use. Any program that disturbs the CRUNCH vector or the memory area where the Proofreader resides will probably crash the system without delay.

When using the Proofreader with another utility, you should disable both programs before running a BASIC program.

\title{
MultiMemory For Commodore 64 And Apple
}

\author{
Patrick Parrish, Programming Supervisor
}

This short utility partitions free memory so several BASIC programs can be loaded into your computer at once. Among other things, it's a great aid during program development-you can keep a couple of BASIC programming utilities at hand as you work, or test alternate versions of new routines before adding them to your main program. The Apple version works on all Apple II series computers with either DOS 3.3 or ProDOS.

The idea of partitioning memory into several modules 'which can contain separate programs is not new-Charles Brannon relied on BASIC pointers to split the PET into four 8 K blocks with "Quadra-Pet" (COMPUTE!, June 1981), and Feeman Ng later partitioned the 64 into three 12 K blocks with "Triple 64" (COMPUTE!'s GAZETTE, April 1985). Much like these earlier programs, "MultiMemory" divides free memory in your Commodore 64 or Apple into independent workspaces. Three partitions are set up in the 64 , and four in the Apple. As before, you can load different BASIC programs into the computer at once. These could be utilities, applications, or games. And, once again, you can save and load programs from any of these areas without affecting the others.

But MultiMemory goes one step further. Not only are the BASIC programs in each module protected from one another, but the variables generated by each are protected as well. Any program can
change a variable's value without affecting identically named variables that may exist in other partitions. That means there's even less chance of conflict between the programs, allowing you more flexibility when using MultiMemory.

\section*{Entering MultiMemory}

The BASIC languages in the 64 and Apple were both written by Microsoft, Inc. and thus share numerous similarities. Nowhere is this more clearly seen than in a section of memory called zero page (locations \(0-255\) ), where many BASIC pointers are stored. If you compare detailed memory maps for these computers, you'll find that many zero-page pointers, though located at slightly different addresses, are the same on these two machines. MultiMemory takes advantage of this by using identical zero-page pointers in the 64 (locations 43-56) and in the Apple (locations 103-116) to split up free memory. As a result, the 64 and Apple versions of MultiMemory are alike in many ways.

Whether you have a 64 or an Apple II series computer, MultiMemory is entered in the same fashion. Both versions contain short machine language routines entered by a BASIC loader. Carefully type Program 1 for the 64 or Program 2 for the Apple and save a copy to disk or tape before running it for the first time.

When you run MultiMemory, line 100 sets the top of BASIC memory for the first partition. This is memory location 16384 (64*256)
on the 64 and location 8192 on the Apple (we'll see why later).

Line 110 POKEs the machine language routine in lines \(150-330\) into a safe place in memory. On the 64, it's placed at the top of BASIC RAM (40769) just below BASIC ROM (40960). On the Apple, it resides at location 38251 just below DOS (38400). These areas are relatively safe from memory conflicts.

Line 120 checks to see if the machine language data has been correctly typed. Lines 130 and 140 place zeros in three sequential locations at the start of each memory module. The first zero is required to indicate the start of BASIC. The second and third zeros NEW each memory module. Finally, the NEW command in line 140 clears the BASIC loader from memory and leaves us in module 1.

\section*{Three Or Four Computers}

To access any module on the 64, type SYS 40769 and press RETURN. The cursor will disappear. Now, pick a work area by typing 1, 2 , or 3 . For a test, let's choose partition number 2. A tone sounds as the partition number is displayed on the screen. That's all it takes to switch modules.

If you're using an Apple, type CALL 38251 and press RETURN. Choose among work areas 1 to 4 . Again, for a test, specify number 2. A tone sounds, the partition number is displayed, and we're ready to program.

When you type LIST, you'll see that module 2 is empty. Now type PRINT FRE(0) to determine how much memory is available in this
module. The 64 should show about 16 K free, and the Apple about 8 K . On either machine, there is plenty of room for a short BASIC program and its variables. To see that both a program and its variables remain intact within a particular module, let's enter and run a program in module 2 and then do the same in module 1 .

While in module 2, type and run this program:
10 REM EXAMPLE 2
20 AS = "MODULE \# \({ }^{\prime \prime}\)
30 FOR I=1 TO 20:NEXT I
After running this program, type PRINT A\$,I and press RETURN. You should see this:

\section*{MODULE \#2 21}

Save this program to disk or tape with the filename "P2."

Now let's go to another module. Before we do this, list the program in module 2 so that it's at the bottom of the screen. Now type SYS 40769 on the 64 or CALL 38251 on the Apple and choose module 1.

\section*{Independent Variables}

After entering module 1, type LIST to prove that our first program has been left behind in module 2. Again, if you wish, type PRINT \(\operatorname{FRE}(0)\) to determine the amount memory available in this module. The 64 should show about 14 K and the Apple approximately 6 K .

Program "P2" should still be on the screen. Even though it was listed in module 1, it remains visible if you switch partitions without clearing the screen. This makes it possible to copy program lines from one module to another with the screen editor. Simply use the screen editing keys to cursor up to line 10 . Change the 2 in this line to a 1 and hit RETURN to enter this line in memory (Apple users must cursor to the end of the line before pressing RETURN, of course). Line 10 is now copied into memory in module 1 without disturbing line 10 in module 2.

If the BASIC screen prompts do not obscure the other program lines, you can copy them to module 1 in the same manner. At any rate, lines 20 and 30 should read:

\footnotetext{
20 AS="MODULE \#1"
30 FOR I=1 TO 10:NEXT I
}

As you did before, run the program and then type PRINT A \(\$\), I. The result is:

\section*{MODULE \#1 11}

Save this program on disk or tape as "P1."

Now, go back to module 2 with SYS 40769 or CALL 38251 and type LIST. You should see program "P2" on the screen unchanged. Print the values for \(\mathrm{A} \$\) and I. You'll see they still have the values they had when we left module 2 .

\section*{Applications}

As you can imagine, this process can be very valuable if you're writing and debugging your own programs. Suppose you're writing a program in module 1 and you need a subroutine from a BASIC program you have on disk. Maybe you aren't sure which disk the program is on. On the 64, normally you'd have to save the program currently in memory before looking at the disk directory, because the directory overwrites the BASIC workspace. (On the Apple, this wouldn't be a problem, since the disk catalog is not loaded into the BASIC workspace.)

With MultiMemory, you can nimbly jump to another module, load the directory there to find the program you need, and then load it into that module or the third module, leaving the directory intact. And, once you've found the subroutine you need from your earlier program, you can list it on the screen, shift back to the first partition, and copy the lines by RETURNing over them.

Now suppose that some bug in your program keeps the subroutine from working as you expected. Since variables retain their values within each program module, you can test each routine separately, compare the resulting variables, and make changes to your working version where needed.

With all this jumping from module to module, you might loose track of which partition you're in. To find out, you can type PRINT PEEK(40914) on the 64 or PRINT PEEK (38339) on the Apple.

In addition to aiding program development, MultiMemory can be used to hold a few BASIC programs that can be run individually. For
instance, you might have a series of BASIC programs that, in sequence, manipulate data stored on disk. The first program could read in the data, manipulate it, and then write the results back to disk. In turn, a second or third program (or on the Apple, even a fourth) stored in the other workspaces could do the same. Or you could designate one BASIC workspace for data storage, much like a RAM disk.

Before undertaking any sophisticated programming applications with MultiMemory, however, you should consider how it works and keep in mind a few restrictions on its use.

\section*{Memory Ceilings}

As mentioned earlier, MultiMemory uses a series of BASIC pointers in zero page to set up each workspace. The values required by these pointers for each module are stored in a lookup table at the end of the program. Whenever you SYS or CALL MultiMemory, it stores the current zero-page values in positions within this table which correspond to the current module. The program then waits for you to specify the next module.

When you pick a module, MultiMemory reads the zero-page pointer values for the module and places them in their proper zero page locations. The pointers transferred are the starting addresses for the location of the BASIC program, the array and nonarray variables, the string variables, and the top of BASIC memory.

The barriers separating the partitions were selected to keep MultiMemory compatible with most programs. On the 64 , the first module runs from memory locations 2048-16383; the second, from 16384-32767; and the third, from 32768-40768. Partitions are placed on 16 K boundaries because the 64 's VIC-II chip can address only one 16 K block at a time. The VIC-II chip is responsible for handling the 64 's video display-such things as sprite shapes, screen memory, and character data.

On the Apple, the first module runs from memory locations 20488191; the second, from 8192-16383; the third, from 16384-27317; and the fourth, from 27318-38250.

Note that the location of module 2 coincides with the Apple's first high-resolution graphics page. That means any programs which use the hi-res graphics page should be loaded into another module. And, of course, any programs loaded into module 2 will likely be erased if a program in another module uses the hi-res page.

\title{
Experimenting With SID Sound
}

\author{
Mark A. Currie
}

This versatile program for the Commodore 64 lets you experiment with a wide variety of sound effects and listen to how they sound in a preprogrammed song.

The Commodore 64's SID (Sound Interface Device) chip offers the ability to create a great number of rich, distinctive sounds. But sound programming involves so many different parameters (controlling values) that testing even a few different combinations can consume a lot of time. This program lets you change and experiment with any of the SID parameters quickly and easily. Once you have designed a sound, you can test its actual effect by playing it in a preprogrammed song.

Type in and save a copy of the program before running it for the first time. When you type RUN, the main menu displays 12 choices:

Option 1 lets you select one of four different SID waveforms-triangle, sawtooth, pulse, or noise. Each has its own distinctive tone. If you select the pulse waveform you must also set the pulse width to some nonzero value with Option 2. Options 3 and 4 permit you to adjust the ADSR (attack/decay/sustain/ release) envelope of the sound. Each of the four ADSR parameters can be set separately to any number from 0-15.

Attack controls the rate at which the sound rises from zero to full volume. Decay controls the rate at which it falls from the level it reached at the end of the attack cycle to the volume level set by the sustain setting. Sustain sets the volume level the note will maintain from the end of the decay cycle until the note is turned off. And release controls how fast the note fades away after it's turned off. Since all four ADSR settings con-

> 1 WAVEFORM
> 3 ATTACK/DECAY
> 5 LOUDNESS
> 7 RING MODULATION
> 9 PLAY MUSIC
> 11 QUIT

2 PULSE WIDTH
4 SUSTAIN/RELEASE
6 SYNCHRONIZE V1 to V3
8 FILTERS
10 ZERO VARIABLES
12 LIST OF EFFECTS

The first eight options let you design a sound by changing one or more of the SID chip's parameters. In each case, the computer tells you what range of values is allowed and prevents you from entering illegal values. If you select an option and decide not to change anything, press RETURN without entering any value. Let's look at each option in turn.
tribute to the ultimate result, it may take some experimenting to find exactly the envelope you want. Option 5 sets the SID's master volume control, accepting values from 0 (silence) to 15.

As you may know, the SID chip has three separate voices or tone generators. Option 6 permits you to synchronize two of these voices (1 and 3), producing effects
which neither voice could produce alone. Note that voice 3's frequency must be set to some nonzero value before synchronization can work. This program lets you set voice 3's frequency to an unchanging value or to values that vary along with voice 1 's frequency changes. Option 7 selects ring modulation: This effect is generated much like synchronization, but produces quite different effects. Again, you must set voice 3's frequency to a static value or an offset of the frequency for voice 1 .

Note that while this program uses only voices 3 and 1 for synchronization and ring modulation, you may use these effects with other voice combinations in your own programs. In this case, voice 3's frequency affects voice 1 . With the same techniques, you can affect voice 2 by voice 1's frequency, or affect voice 3 by voice 2 's frequency. No matter which combination is used, you must supply frequency values for both of the voices involved.

Option 8 controls the filter, allowing you to change six different parameters. You may turn four different types of filters on or off and set the overall cutoff frequency and resonance for the filters. Filtering permits only certain specified frequencies to pass unchanged. Frequencies outside the specified range are much quieter or inaudible. You can choose from four types of filters: low-pass, band-pass, high-pass, and notch-reject. When a filter is on, you can also choose an overall filter resonance value.

Resonance emphasizes frequencies near the cutoff frequency of the filter.

\section*{Customized Music}

When you select Option 9, the program plays a song using the sound you have designed: Don't be discouraged if the results aren't exactly what you expect at first. Sometimes a minor change in only one or two parameters (particularly those controlling the ADSR envelope) makes a big difference in the ultimate effect.

Option 10 clears all sound parameters to zero to clear the slate for a new sound. Note that the SID chip produces silence when every parameter is zero: The least you must do to produce a sound is turn on a waveform, set the volume to a nonzero level, and define some sort of ADSR envelope. To help you get started, this program begins by choosing maximum volume, a pulse waveform (with pulsewidth of 2048), an attack value of 1 , and a decay of 9 .

After designing a sound that you like, you may wish to use it in a program of your own. Option 12 generates two lists for that purpose. The first list summarizes the sound parameters currently in effect. The second list includes all the SID control locations and indicates which values to POKE into each register to reproduce the current sound. Although this program makes only one voice audible, you can achieve even more interesting effects by activating more than one voice at a time.

\title{
Mousify Your Applesoft Programs
}

\author{
Lee Swoboda
}

Here's the first installment of a twopart tutorial on interfacing and using a mouse with your Apple II computer. Though a mouse is preferred, you can use the techniques shown here to substitute a joystick or game paddles for the mouse.

Allow me to introduce a new word-mousify. Don't try to look that up in a dictionary-it's not there, at least not yet. Though Apple didn't invent the mouse, their Macintosh was the first popular home computer that used one; and it has changed the way that we interface with computers. So the need for the word mousify-to add mouse control to computer hardware or software-may grow.

\section*{A Mouse For Apple II}

Apple II computers don't come with a mouse, but it's now possible to add one. If you have an Apple II, II + , or IIe, you'll need an interface card (Apple product A2M2050, \(\$ 149.95\) including the mouse). The interface is built into the IIc, so you only need to buy the mouse device (Apple product A2M4015, \$99.95).

Attaching a mouse to your Apple II is only half the battle. To your computer, a mouse is merely another input device, like a joystick. Many new programs have the ability to accept mouse input. But there are thousands of existing programs that were written before the mouse appeared on the scene. Most commercial programs are written in ma-
chine language and protected from unauthorized access so, unless you are an expert machine language programmer, you won't be able to mousify them. However, Applesoft BASIC programs can easily be mousified.

Pages 35-40 of the AppleMouse II User's Manual, which comes with the mouse, give a brief description of how to use the mouse in a BASIC program. But the two examples are trivial and the text fails to mention some of the "features" that make mousifying an Applesoft program difficult. For example, you must use the INPUT statement to obtain mouse position parameters. Unfortunately, the INPUT command erases one line of screen text. In addition, your program must set the computer to receive input, which disconnects the keyboard. Mixing mouse and keyboard input requires switching input control between the mouse and the keyboard. Not only that, you have to use GET statements for keyboard input, which can be exasperating. Using these techniques quickly turns your BASIC program into a Rube Goldberg contraption of INPUTs, GETs and PRINT D\$'s. But there's a better way to handle the mouse.

Fortunately, Apple's input and output (I/O) are memory-mapped, meaning that the keyboard and each character on the 40 -column screen are at specific locations in Apple's main memory. Applesoft's PEEK and POKE commands let us examine and change characters on the screen without having to use

INPUTs, GETs or PRINTs. This is especially important when using the mouse, since it lets you zoom quickly to any point on the screen to change a character, rather than perform complex string manipulations.

\section*{Practical Application}

Let's see how this works. Type in and save Programs 1 and 2, then load and run Program 2, which creates a text file for Program 1 to read. When that's done, load and run Program 1. You'll see an input screen, typical of what might be used in an address book program that lets you store and recall names and addresses. (Of course, this program is just for demonstration; you can't use it to create a real address file.)

In a typical program, the computer would make you reenter an entire line to correct a misspelling or other error. Program 1 lets you point directly at an error with the mouse, and change only the incorrect character. The initial screen display should contain this information:

\section*{ENTER INFORMATION}
\begin{tabular}{|c|c|}
\hline FIRST NAME & COMPUTE! \\
\hline LAST NAME & REEDER SERVICE \\
\hline STREET & P.O. BOX 2141 \\
\hline CITY & RANDOR \\
\hline STATE & PA \\
\hline ZIP & 19089 \\
\hline TELEPHONE & 1-800-334-0868 \\
\hline ERASE & UIT DONE HELP \\
\hline
\end{tabular}

Notice that the word READER is misspelled REEDER. That's the mistake you'll correct. Also notice there are three flashing rectangles
on the screen．The rapidly flicker－ ing rectangle in the upper－right cor－ ner is produced when Program 1 obtains mouse input（lines \(10150-10160\) ）．This effect is always present，but is unimportant to the present discussion．The flashing C at the beginning of the word COM－ PUTE！is the cursor．The blinking reflex（ \({ }^{( }\)）in the upper left corner of the screen is the mouse pointer．The mouse moves the mouse pointer around the screen．

Move the mouse so the mouse pointer replaces the second E in REEDER and press the mouse but－ ton．The computer immediately moves the cursor to the same spot． Now type the letter A（upper or lower case）to correct the spelling mistake．That＇s all you need to do to correct the error．You can also use the arrow keys to move the cursor（Apple II uses the CTRL－J and CTRL－K keys to simulate the up and down arrow keys of the IIe and IIc）．But the mouse moves the cursor much more rapidly，and is far more intuitive to use．

Now move the pointer to the word DONE in the strip menu at the bottom of the screen，and press the button．The computer reads the information from screen memory and，in this case，redisplays the up－ dated information．Of course，in a working program you would re－ place lines 30120－30190 with rou－ tines that store the data for later recall．You can move the mouse pointer or cursor anywhere on the screen，but line 10710 of the pro－ gram prevents you from typing anything outside the text area．

\section*{How The Program Works}

Let＇s take a closer look at the signif－ icant portions of Program 1．Lines 130 and 10000－10830 are the most important．Line 130 sets the sensi－ tivity of the mouse．When MI has a value of 20 ，the pointer moves to any part of the 40 －column screen as the mouse moves within a \(5 \times 8\) inch area．Give MI a larger value to make the mouse less responsive．

Lines 10070－10090 activate the mouse．Input control is trans－ ferred from the keyboard to the mouse，until line 20030 returns control to the keyboard．Lines 10150－10270 calculate the horizon－ tal and vertical position of the
mouse and determine whether the mouse button has been pushed． Line 10170 and lines \(10440-10760\) handle input from the keyboard． Note that input control remains with the mouse at this point：The program does not use the statement PRINT D\＄＂IN\＃0＂to return control to the keyboard．This is the key to the simplicity of Program 1，since it avoids the problems normally en－ countered when using GET and PRINT commands with DOS．

Line 10220 and lines 10230－10270 move the cursor to the same position as the mouse pointer when you press the mouse button．Lines 10320－10390 posi－ tion the mouse pointer and return to line 10150 to read the mouse again．If you don＇t press a key or the mouse button，the computer stays in the loop from 10150 to 10390，reading the mouse and re－ positioning the mouse pointer． Lines 10590－10620 position the cursor．This routine is activated only when you press an arrow key or the mouse button．Lines 10640－10690 change all upper－ and lower－case and all inverse characters to flashing．

\section*{Substituting A Joystick Or Game Paddles}

If you don＇t have a mouse，you can use a joystick（or，less conveniently， game paddles）to achieve the same effects．With a few modifications， Program 1 can be made to accept joystick or paddle input．Here are the steps to follow：
1．Delete lines 120，130，10001－ 10090 and 20220.
2．Modify the following lines as shown：
CB 1 （15 X （ \(=\) PDL（ \(\varnothing\) ）
441 1516 Y \(5=\) PDL（1）
Af \(1617 \varnothing\) IFBø＞127THEN1 \(944 \varnothing\)
A9 \(1 \varnothing 18 \emptyset \quad Y \emptyset=\) INT \((Y \emptyset / 1 \varnothing)+1\)
47 1ø2ஏø Xg＝INT \((X \varnothing / 6)+1\)
61 1ஏ22の IFBg＜128THEN1ஏ32の
32 2øø3ø REM
3．Add the following lines：
\(6016165 \mathrm{Bg}=\operatorname{PEEK}(-16384)\)
541 б215 \(\mathrm{B} \emptyset=\operatorname{PEEK}(-16287)\)
After making these changes， resave Program 1，using a different filename to distinguish it from the original version．When you run it， the joystick moves the mouse pointer around the screen and the
button works just like the mouse button．At this point you might wonder why anyone would buy a mouse，since a joystick or game paddle seems to work as a substi－ tute．Part of the reason is simply preference－many people find that a real mouse＂feels＂better and is therefore more convenient than a joystick．More significantly，most commercial programs that accept mouse input do not recognize input from a joystick or paddles．If you＇re writing programs strictly for your own use，a joystick may serve the purpose；but if you buy commercial software that requires a mouse，you may have no choice．

Using a mouse is a new expe－ rience for many Apple II owners．I hope this program inspires you to mousify some of your own pro－ grams．In Part 2 of this article we＇ll expand the capabilities of Program 1 to let you use the mouse to delete and insert blocks of text．

\section*{Program 1．Apple II Mouse Demonstration}

\title{
Atari BootStuffer
}

\author{
Randy Boyd
}

This short, handy program for all eight-bit Atari computers lets you store as many as ten boot programs on a single disk and execute any of the programs just by pressing one key. A disk drive is required.

If you're like many Atari computer users, you probably have a number of disks that contain nothing but a single boot program. Even if you don't mind the expense of storing only one program per disk, that's not a very efficient arrangement. "Atari BootStuffer" allows you to put as many as ten boot programs on a single disk (depending on how long each program is), and still use each program as if it were alone on the disk.

Type in Atari Bootstuffer from the listing below, and save it. As listed here, the program works on an Atari 800 with an 810 disk drive. If you have an XL or XE model, change the numbers in line 750 as shown in the REM in line 740. If you have a 1050 disk drive with DOS 2.5 or 3.0 and wish to use enhanced-density, change lines \(1140,1170,1300\) and 1340 as indicated in the REM lines in the program listing. Changing those lines gives you 1040 sectors per disk (of course, this is not possible on an 810 disk drive, which doesn't support enhanced-density).

\section*{Creating A BootStuffer Disk}

Before running Atari BootStuffer, format a disk to be used as the special BootStuffer disk. Now run the program and insert the freshly formatted disk in the drive. When you press the space bar, the screen turns green and the drive spins for
about one minute. When the screen turns red, the special disk is ready to use. Reboot the system: The computer loads and executes a machine language program which lets you use the BootStuffer disk. When the prompt appears, you can press S to save a program on the disk or press \(L\) to load and run a program.

Since you just formatted the disk, it doesn't yet contain any programs you can load. Press \(S\) to choose the save option. The program indicates how many sectors are free in the current block and asks whether you want to load the target program from disk (press D) or cassette (press C). From that point onward, simply follow the prompts on the screen: The target program is loaded into memory and saved on the boot disk. If a load error occurs, the screen fla shes red and the program starts over again. By repeating this process, you can save as many as ten boot programs on one disk (of course, the number of programs you can fit on one disk depends on how long they are).

BootStuffer prepares the disk by dividing it into ten blocks numbered \(0-9\), each containing 255 sectors. Since it uses the operating system boot routines, this program is not able to read sectors 256,512, 768 or 1024. The BootStuffer code occupies the 13 lowest-numbered sectors on the disk, so a singledensity disk can store programs only in sectors 13-255, 257-511 and 513-720. An enhanced-density disk with 1040 sectors can use all of the single-density sectors plus sectors 513-767, 769-1023 and 10251040.

It's important that you arrange the boot programs to fit into the Bootstuffer disk without wasting
too many sectors. The program tells you how many sectors are left in the current block, and how many sectors are in the program you're trying to save. If a program is too large to fit in the current block, BootStuffer prompts you to save a smaller program in that block. If you don't have a smaller program, you can press N to advance to the next block. However, skipping to the next block wastes the free sectors remaining in the last block. If you try to save a program that requires more space than is left on the disk, BootStuffer generates a DISK FULL message and permits you to save a smaller program in the same space.

When you name a program to be saved on the disk, make sure the name is ten characters or less. Once you have saved as many programs as you want, put the BootStuffer disk in the drive and reboot the system, then press L to choose the load option. The contents of all ten blocks are displayed, and you're prompted to choose which program you want to execute. Press a number key from 0-9: The program in that block automatically loads from disk and executes. Blocks that don't contain a program are marked as empty. Don't select an empty block from the load menu: You may cause the system to crash.

\section*{Atarl BootStuffer}

For instructions on entering this listing, please refer to "COMPUTEI's Guide to Typing In Programs" published in this issue of COMPUTEI.

\title{
Requester Windows In Amiga BASIC
}

\author{
Tom R. Halfhill, Editor
}

Here's how to add your own custom requester windows to any Amiga BASIC program. Like dialog boxes on the Macintosh, requester windows allow your programs to flag errors or request confirmation before carrying out important functions. The routine is written for Microsoft Amiga BASIC, which is now being shipped in place of MetaComCo ABasiC and is available as an upgrade to early Amiga owners.

Amiga BASIC is the most powerful BASIC interpreter supplied with any personal computer on the market. Written by Microsoft, it combines in a single language almost every feature found in IBM PC Advanced BASIC plus Microsoft BASIC for the Macintosh. In fact, many IBM BASICA and Macintosh BASIC programs will run on the Amiga with minor modifications.

However, Amiga BASIC does lack two key statements found in Macintosh BASIC: DIALOG and BUTTON. Both are important for writing BASIC programs which retain the mouse-and-window user interface common to the Macintosh and Amiga Workbench. Fortunately, both commands can be simulated fairly easily with Amiga BASIC's WINDOW and MOUSE statements.

In Macintosh BASIC, the DIALOG command lets a program open a dialog box (a small window) like those displayed by the Macintosh's operating system whenever the user must choose between two or more options. Dialog boxes also flag errors and alert users when they're about to activate a function that has irreversible conse-quences-such as quitting a program without saving the data on disk. For example, if the user pulls down a menu and selects Quit, a dialog box might open up and ask, "Quit program? (Data file not saved.)" Below this message is usually a pair of small boxes or circles called buttons which might be labeled OK and CANCEL. Pointing and clicking the mouse on the OK button exits the program; pointing and clicking on the CANCEL button cancels the Quit function and returns to the main program so the user can save his data if desired.

In Amiga BASIC, the DIALOG and BUTTON commands must be simulated by a routine that uses the WINDOW and MOUSE statements. For greater convenience, the routine can be written as a subprogram, another advanced feature included in Amiga BASIC. Sub-
programs are similar to subroutines, except they can have local variables. These are variables which are independent of the main program. For instance, if your main program uses a variable X for some purpose, a subprogram can also use a variable named \(X\) and it is treated as a separate variable. If the subprogram changes the value of its variable \(X\), the main program's variable \(X\) is unaffected, and vice versa. On the other hand, a subprogram can also specify shared variables, sometimes known as global variablesthose which are common to both the subprogram and the main program.

A major advantage of subprograms is that you can build up a library of useful routines on disk and add them to any new programs you write. This saves you the trouble of writing the same subprograms again and again. Although you can do the same thing with ordinary BASIC subroutines, there's always the chance that a subroutine variable might conflict with an identically named variable in your main program. Since subprogram variables are local, you're freed from this worry. Subprograms are truly programs within a program.

\section*{The Requester Subprogram}

On the Amiga, dialog boxes are called requesters. Probably the most frequently encountered requester is the one that pops up when the Amiga asks you to insert a different disk. For the sake of consistency, an Amiga requester generally appears as a small window in the upper-left corner of the screen, has a title bar labeled System Request, has two or three buttons, does not have a resizing gadget or close gadget, and cannot be moved elsewhere on the screen.

The "Requester Window Subprogram" listed below duplicates most of these features. It creates a window that appears in the upperleft corner of the screen (or up to the full width of the screen in lowresolution modes); the window has a title bar labeled Program Request
(to distinguish it from System Request windows); there is no resizing gadget or close gadget; and the window cannot be moved elsewhere on the screen. Unlike system requesters, this requester always displays two buttons, and they're always labeled OK and CANCEL.

The subprogram lets you display one or two lines of your own text in the Program Request window. The maximum number of characters allowed in each line depends on whether the Amiga has been set for 60 - or 80 -column text with the Preferences tool. If Preferences is set for 60 columns, each requester line can be up to 31 characters long. If Preferences is set for 80 columns, each line can be up to 39 characters. (You can adjust the subprogram for either mode by changing a single program state-

\section*{Requester Window Subprogram}

RequesterSub:
SUB Requester STATIC
SHARED requestl\$,request2\$,answer:' Global variables.
, Add screen parameter if needed to next line.
WINDOW 2," Program Request",(0,0)-(311,45),16
, Following lines truncate prompts if too long.
, If Preferences is set for 60 columns,
, use maxwidth = INT(WINDOW(2)/10) for next line;
, otherwise use maxwidth=INT(WINDOW(2)/8).
maxwidth = INT(WINDOW(2)/10)
requestl\$=LEFT\$(request1\$,maxwidth)
request2 \(\$=\) LEFT \(\$\) (request2\$, maxwidth)
PRINT requestl\$:PRINT request2\$
, This section draws buttons.
LINE ( 12,20 )-( 50,38 ), 1, b
LINE (152,20)-(228,38),1,b
LOCATE 4,1:PRINT PTAB(20);"OK";
PRINT PTAB(160);"CANCEL"
, This section gets input.
reqloop:
WHILE MOUSE(0) \(=0\) :WEND:' Wait for button click.
\(\mathrm{ml}=\mathrm{MOUSE}(1): \mathrm{m2}=\mathrm{MOUSE}(2)\)
IF \(\mathrm{ml}>12\) AND \(\mathrm{ml}<50\) AND m2>20 AND \(\mathrm{m} 2<38\) THEN answer \(=1\) :' OK was selected. LINE ( 12,20 )-( 50,38 ), 1,bf:' Flash OK box.
WHILE MOUSE (0)<>0:WEND:' Wait for button release. WINDOW CLOSE R:EXIT SUB ELSE
IF \(\mathrm{ml}>152\) AND \(\mathrm{ml}<228\) AND m2>20 AND mz<38 THEN
answer \(=0\) :' CANCEL was selected.
LINE (152,20)-(2288,38),1,bf:' Flash CANCEL box.
WHILE MOUSE(0)<>0:WEND:' Wait for button release. WINDOW CLOSE \(2: E X I T\) SUB ELSE GOTO reqloop
END IF
END IF
GOTO reqloop
END SUB

A short subprogram lets you quickly and easily add custom requester windows to your own Amiga BASIC programs.
ment; see the remarks in the listing.) If you try to display a line of text which exceeds these limits, the subprogram leaves off the extra characters. Since you won't know how Preferences is set if you're writing programs that might be used by other people, it's safest to assume 60 columns and restrict each line of your message to 31 characters.

Opening a Program Request window is this simple:
request1\$="This is the first line."
request \(2 \$=\) "This is the second line."
CALL Requester
The two lines of your message are defined in the string variables request \(1 \$\) and request \(2 \$\), and the CALL statement runs the subprogram (similar to GOSUB). The subprogram opens the requester window and waits for the user to click on the OK or CANCEL button. Clicks outside the buttons are ignored, although a click outside the requester window itself deselects it as the active window. It can be reselected, of course, by clicking within the window.

If the user clicks on OK , the subprogram returns a value of 1 in the variable answer. If the user clicks on CANCEL, answer equals 0 . In either case, the subprogram closes the requester window after the button click and passes control back to the line following the CALL Requester statement. By testing answer, your program can branch to different routines to handle the user's response as required.

\section*{Hints For Use}

Here's an example. Suppose your BASIC program sets up a Project
menu with a Quit selection (a consistent feature in Amiga software). When your MENU statement detects that Quit has been selected, it can GOSUB Quit:
Quit:
MENU OFF:CLS
request1S =" "Quit program?"
request \(2 \$=\) " (OK exits to Workbench or CLL.)"
CALL Requester
IF answer \(=0\) THEN RETURN SYSTEM

If the user selects Quit by accident or changes his mind, he can click on CANCEL and no harm is done-the Quit routine merely RETURNs. Otherwise, a click on OK stops the program and exits BASIC with the SYSTEM command. Of course, you could also include a check to see if any data created with the program has been saved, and if necessary prompt the user to save it before quitting.

There are only two more details to keep in mind when using the requester routine. First, the WINDOW statement near the beginning of the subprogram opens WINDOW 2. If there's a chance that your program might already have two or more windows open when the requester is called, change this statement to WINDOW 3 , or WINDOW 4, or whatever is necessary to avoid a conflict.

Second, the WINDOW statement defaults to the primary (Workbench) screen. That means the requester window always pops up on the primary screen. If your main program creates a secondary screen with the SCREEN statement, you'll want the requester window to appear on that screen instead of the primary screen. Otherwise, the requester will be invisible. To make the requester window appear on your program's secondary screen, append the screen's number to the WINDOW statement.

For instance, if your program creates a secondary screen with a statement such as this:
SCREEN 1,320,200,1,1
change the WINDOW statement in the requester subprogram as follows:

\section*{WINDOW 2,"Program Request",(0,0)(311,45),16,1}

This makes sure the requester will be visible.

\section*{Softkeys}

\section*{For}

\section*{Atari BASIC}

Raymond Citak

This labor-saving utility adds automatic line numbering and 19 preprogrammed "soft" keys to your Atari computer. Even better, the soft key assignments are compatible with COMPUTE!'s "Automatic Proofreader." For any Atari 400/800, XL, or XE computer with at least 48 K RAM.

If you write your own BASIC programs or enter the programs listed in COMPUTE!, you'll welcome any utility that cuts down on your typing time. "Softkeys For Atari BASIC" does exactly that-it gives you automatic line numbering and 19 preprogrammed soft keys that enter an entire BASIC word with just one keystroke. And there are two extra soft keys you can program for your own use.

Type in the program below and save it on disk or tape before running it for the first time. If you plan to use it along with the "Automatic Proofreader" to type in a COMPUTE! program, you should load and run Automatic Proofreader at this point. (Of course, this
program works on its own, even if you're not using the Proofreader; but when the two are used together, you must install the Proofreader first.)

Now load and run the Softkeys program. It begins by asking you for the starting line number of the program you'll be typing in. Enter that number and press RETURN. Now you're asked to enter the increment (how much the line number increases between one line and the next). Most programs published in COMPUTE! are numbered in increments of ten, but you should always check the program listing to make sure. This number can be changed if the listing later changes to a different increment or skips some line numbers.

\section*{Automatic Line Numbering}

After you enter this information, Softkeys installs its machine language portion in memory, deletes its BASIC portion, and leaves the computer ready for you to use. On the line below the READY prompt you'll see the first line number followed by a space. Type in the first line from the program listing, then
press RETURN to enter it in memory. The computer automatically prints the next line number and waits for you to enter the next line.

If the computer detects an error in the line, it prints the line again and shows where the error occurred. To retype the line, simply press SHIFT-DELETE, type in the correct line number and reenter the line. If you prefer, you can move the cursor back to the old line as usual, correct it, and press RETURN again. Just as in normal screen editing, the cursor can be anywhere on the line when you press RETURN.

The SHIFT-DELETE key combination also lets you perform several other tasks. If the program listing skips line numbers, press SHIFT-DELETE, then enter the new line number and continue typing as before. You can also use SHIFT-DELETE to enter any BASIC command from direct mode. For example, you may want to continue typing a program that you've partially entered and saved. Run Softkeys and answer the prompts as you did when you began typing the program. When the READY prompt comes back, press SHIFTDELETE, then enter the command you would ordinarily use to load the program. After the program loads, the computer finds the last line number used in the program and automatically continues numbering from that point.

If you press SHIFT-DELETE and then change your mind, press RETURN without typing anything else: The correct line number reappears.

At times you'll need to change the line number increment midway through the program. To do this, press BREAK to disable Softkeys, then enter a USR statement in this format:

\section*{\(\mathrm{U}=\mathrm{USR}(39300\), line number, increment)}

The increment parameter specifies the desired new increment value, which takes effect after the next line is entered. The line number parameter must be included, but it has no effect. The program continues with the line number in use before the USR. For example, if you've been numbering lines by tens until you reach line 500 and wish to switch to increments of five, get a blank line by pressing SHIFT-DE-

LETE when the computer prints 500, then enter the statement \(\mathrm{U}=\mathrm{USR}(39300,100,5)\). After this, the prompt for line 500 returns, but the next line number is 505 .

\section*{Softkey Assignments}

A softkey is a preprogrammed key combination that lets you print a complete BASIC command with a single keystroke. This program creates a number of softkeys that let you enter commonly used commands quickly and easily. The softkeys are all entered by pressing CTRL along with another key. The accompanying table lists all of the built-in softkeys.

When Softkeys is active, you can enter any of the 19 keywords shown in the table by pressing CTRL along with the indicated key. If you press CTRL-F, the computer prints FOR, and so on. This saves typing time and helps eliminate errors (the computer never types PRIMT instead of PRINT, for example). Note that STRIG and STICK both include a left parenthesis.

\section*{Atari Softkeys}
\begin{tabular}{ll} 
Softkey & Command \\
CTRL-A & GRAPHICS \\
CTRL-C & COLOR \\
CTRL-D & DATA \\
CTRL-E & PEEK \\
CTRL-F & FOR \\
CTRL-G & GOTO \\
CTRL-I & INPUT \\
CTRL-K & STICK \\
CTRL-L & LOCATE \\
CTRL-N & NEXT \\
CTRL-O & POKE \\
CTRL-P & POSITION \\
CTRL-R & READ \\
CTRL-S & SOUND \\
CTRL-T & STRIG \\
CTRL-U & GOSUB \\
CTRL-W & DRAWTO \\
CTRL-? & PRINT \\
CTRL-RETURN & RETURN
\end{tabular}

Though 19 softkeys are built into the program, you can add two more of your own. To do this, you'll need to supply new values in the DATA statements in lines 1100 and 1180. Each line contains 10 values. The first value is the keyscan code generated when you press a key. Before you can program your own softkey, you need to know the keyscan code for the key combination you want to use.

For example, let's say you want to program the CTRL-V key combination to print the keyword SAVE followed by a quotation mark (SAVE"). To find the keyscan code for the CTRL-V combination (or any key combination), type the following statements in direct mode (without a line number) and press RETURN:
FOR J=1 TO 1E9:PRINT PEEK(764) :NEXT J

The computer prints the keyscan code for whatever key or key combination is currently pressed. Try pressing different keys to see the numbers change. The number that appears when you press the desired combination is the keyscan code you need to use. In this case CTRL-V generates the keyscan value 144 , so you should replace the first value in line 1100 with 144.

\section*{Encoding The Softkey}

The next nine values in line 1100 represent the ATASCII values of the characters the computer should print when you press the designated softkey. The ATASCII values for the SAVE" character sequence are \(83,65,86,45,34\). Including the keyscan code, that comes to 6 values: Since you don't need the last four values in that line, make them all zeros (this DATA statement must have exactly ten values, even if you don't need to use all ten). When you're finished, line 1100 should look like this:

\section*{1100 DATA \(144,83,65,86,45,34,0,0,0,0\)}

To use your new softkey, simply rerun the program and try it out. By repeating the process, you can change line 1180 to add another, giving you a total of 21 softkeys. When programming a new softkey, note that you must include a space (character 32) if you want the cursor to move right one space after printing a keyword.

Occasionally, a program requires you to type in a character that requires a CTRL-key combination already used by Softkeys. Disable Softkeys by pressing BREAK, then enter the line. After that's done, you can reactivate the utility with a USR command as described above.

The machine language portion of this program resides in high memory just below the display list
in GRAPHICS 0 ．Use caution if you run a program and later issue the USR command to activate this utili－ ty．If the previous program used high memory for any purpose，the computer may crash．

Once you＇re satisfied with all the softkey assignments，you may want to convert the machine lan－ guage portion of this program to a binary object file on disk．To do this，first run the BASIC portion， exit to DOS，select the Binary Save option，and save memory from \＄9984－\＄9BF1．

\section*{Softkeys For Atarl BASIC}

\section*{BASIC Sound On The Atari ST}

Almost any music or sound effect can be created with the WAVE and SOUND commands in Atari ST BASIC. This article shows how to get started with ST sound and includes sample sound effects and a simulatea piano program. The article is an excerpt from the newly released COMPUTE!'s ST Programmers Guide (by the editors of COMPUTE!, \(\$ 16.95\) ).

The Atari 520ST contains a General Instruments sound chip that has three voices (sound channels) and a range of eight octaves. In fact, it's the same sound chip found in the MSX-standard computers sold in Japan and Europe. The chip's best feature is that it supports envelopeoriented sound-you can create a sound by defining the shape of its envelope. This allows considerable flexibility when designing sound effects and musical instrument tones. However, for programmers, it also requires more work than the SOUND command found in Atari BASIC for the eight-bit computers.

There are two sound commands in ST BASIC: WAVE and SOUND. WAVE controls the makeup of the sound:

WAVE sound type, envelope, shape, period, delay

Some of these parameters require values that toggle certain bits to activate certain functions. If you're not familiar with bit manipulation, refer to Figure 1. The first step is to decide which function(s) you want to select. Then add up the bit values-not the bit num-bers-corresponding to those functions. The resulting number is what you use for that particular parameter in the WAVE statement.

For instance, the first parameter, sound type, controls whether a voice is set to noise, tone, or both. Bits \(0-2\), when set, turn on tone output for voices \(1-3\). Bits 3-5, when set, select noise output for the three voices. Both tone and noise may be turned on at the same time. Here are some example bit values:
WAVE 1-turns on tone for voice 1 WAVE 3-turns on tone for voice 1 and voice 2
WAVE 8-turns on noise for voice 1 WAVE 15-turns on tone and noise for all three voices

Bits \(0-2\) of envelope determine which of the three voices is controlled by the envelope generator. If a bit is set, its corresponding voice

Figure 1: Bit Values
\begin{tabular}{c} 
Bit numbers \(\rightarrow\) \\
Bit values \(\rightarrow\) \\
\hline
\end{tabular}
is controlled by the envelope generator.

The third parameter, shape,

Figure 2: Available Envelopes

Envelope No. Envelope Shape
0

4

8

10

11

12

13

14
controls the way the sound's volume rises and falls. Figure 2 gives the possible values for this parameter and shows the shape of the subsequent sound.

Each of the envelope-shape drawings is a graph of volume over time. Take a close look at envelope zero and imagine what kind of sound it would make. The first thing to notice is that as soon as the sound begins, volume is at maximum. As time passes, the volume slowly fades away until it reaches zero. This type of sound is made by a piano. The hammer hits the string and almost immediately the volume reaches its maximum. The vibration of the string continues and slowly decays.

As you can see from Figure 2 envelopes \(8,10,12\), and 14 are repetitive. The sound continues to surge and fall long after the WAVE command is given.

The period parameter sets the period of the envelope, which is how fast the sound cycles. The larger the period, the longer the note takes to repeat. The last parameter, delay, controls the amount of time the program waits before executing the next BASIC command. Period is measured in one-fiftieth of a second increments. To hear a couple of interesting sound effects produced by WAVE, type in Program 1, "Helicopter," and Program 2, "Ding."

\section*{SOUNDing Off And On}

The other music command, SOUND, turns on one of the voices for a specified duration. Its syntax is:
SOUND voice, volume, note, octave, duration

Voice selects which voice you want to turn on (1-3). Volume can be any number from 0 (off) to 15 (loudest). Note is a number from 1 to 12 and corresponds to the 12 notes in a scale (C, C\#, D, D\#, E, F, F\#, G, G\#, A, A\#, B). The octave ranges from 1 (lowest) to 8 (highest). Duration can be any number from 0-65535. Each increment corresponds to one-fiftieth of a second.

Program 3, "Piano," uses the SOUND and WAVE commands to simulate a piano. Although it's intended as a sound demonstration, it also shows how to use other tech-
niques, such as graphics and reading the mouse from BASIC.

You can run Program 3 in any graphics mode. When the piano keyboard appears on the screen, point to any key with the mouse and press the mouse button. The corresponding note is played.

Before typing in and running Program 3, you must make sure there's enough free memory available in BASIC. At this writing (midDecember), all 520STs were being shipped with the operating system (TOS) on disk. Later versions of the 520ST may be shipped with TOS in Read Only Memory (ROM). Until then, however, TOS must be loaded from disk into Random Access Memory (RAM). Because of the large amount of memory this requires, only a small area of storage remains for BASIC programs. When TOS and BASIC are loaded into a 520 ST with 512 K RAM, only about 5 K is free for BASICenough for a program about 20 lines long. To check how much memory is available, load BASIC and type PRINT FRE(0).

Fortunately, there is a way to increase the amount of free memory by 32 K . Normally, when windows are manipulated, the previous screen is saved in memory because part of it may be covered by a window and have to be restored later. The technique of saving the screen to memory is called buffered graphics. Although it can be quick and convenient, it requires 32 K of memory to hold the screen.

If the buffered graphics option is turned off, 32 K of memory is freed for BASIC. Click on Buf Graphics in the Run menu to toggle the buffered graphics on and off. This should increase free memory to 37986 bytes for BASIC programs.

\section*{Building The Piano}

Let's trace through Program 3 to see how it works. Line 10 dimensions two arrays, B\% and W\%. These hold the note values of the black and white keys, respectively.

Next, the subroutine DRAWSCREEN is called. ST BASIC allows the use of labels instead of line numbers for many of its commands that need to make a reference to a line, like GOTO and GOSUB. Whenever you use a label in a line,
make sure it is separated from the rest of the line with a colon.

The DRAWSCREEN subroutine (beginning at line 150) draws the piano keyboard. The first command of DRAWSCREEN sets the color of all screen output to black. Using only a single color for drawing ensures that the program will work in all graphics modes. The COLOR command also sets the fill pattern to solid. FULLW expands the window to full size, and CLEARW clears it.

The remaining commands of the DRAWSCREEN subroutine create the piano keyboard. Since there is no box drawing command in ST BASIC, we will simulate one using the LINEF command and FILL commands. LINEF draws a line between any two pairs of coordinates. The syntax is:

\section*{LINEF xcoord1, ycoord1, xcoord2, ycoord2}

Next, line 20 calls the subroutine SETARRAY, which reads the note values of the black and white keys into the integer arrays B\% and W\%.

\section*{Reading The Mouse From BASIC}

Now that the screen is set up and the arrays have been initialized, it's time to read the position of the mouse and check if the mouse button is pressed. This is done in the subroutine labeled READMOUSE at line 90 . There is no BASIC command to read the mouse, so we must use one of the computer's Virtual Device Interface (VDI) routines. VDI routines are part of the computer's operating system.

The procedures necessary to call VDI routines are beyond the scope of this article, but basically involve POKEing various parameters into certain memory locations. These memory locations are not absolute addresses-instead, they're accessed via a reserved variable in ST BASIC named CONTRL. The ST automatically assigns an address to this variable which corresponds to the entry point into the VDI. By POKEing values into offsets from this address, various VDI routines can be executed.

The VDI routine for reading the position of the mouse and determining whether the mouse but-
ton is pressed has an opcode of 124, so we POKE CONTRL,124. We must tell the VDI routine that no other parameters are being passed, so two more POKEs are necessary: POKE CONTRL+2,0 and POKE CONTRL \(+6,0\). Now we can call the VDI routine to read the mouse.

To read the horizontal and vertical position of the mouse, PEEK PTSOUT and PTSOUT +2 , respectively. If the mouse button is pressed, PEEKing INTOUT will give a value of 1 ; otherwise, a zero is returned. (PTSOUT and INTOUT, like CONTRL, are also reserved variables for accessing VDI routines.)

The main loop of the piano program (line 30 ) simply waits until a mouse button is pressed. Once the button has been pressed, the vertical coordinates are checked to see if they are in the range of the piano keyboard (line 50). Then the vertical position is used to determine whether the key pressed is black or white (lines 50 and 60). If a black key is pressed, the note is calculated using the array \(\mathrm{B} \%\); otherwise, the array W\% is used.

Line 70 breaks the note value
down into note and octave and then, using the SOUND command, plays the note.

Line 80 sets the envelope shape to zero. This creates a note with a similar shape to a piano's envelope. Program execution is then sent back to the main loop to check the mouse button again and SOUND another note when it is pressed.

\section*{Atari Character Codes}

Last month's discussion about where and how to place things in memory served as a good lead-in to this month's topic: character codes. If you've read the heftier reference material, including COMPUTE! Book's Mapping the Atari, you may have discovered that your eight-bit Atari computer actually uses three different types of codes to represent the various characters (letters, numbers, punctuation, graphics symbols) it works with. All of these codes assign a unique number to represent each character, but the three codes are incompatible with each other because they use different numbering schemes.

The most commonly encountered code is called ATASCII, which
stands for ATari-version American Standard Code for Information Interchange. Except for the so-called control characters-such as carriage return, tab, and so on-ATASCII is compatible with standard ASCII. (Why Atari chose to modify the standard is anyone's guess.) ATASCII is the character code used by PRINT, INPUT, CHR\$(), ASC(), and most external devices such as printers and modems.

For example, in ATASCII (and ASCII), the code for uppercase A is 65. You can verify this in BASIC:

\section*{PRINT CHR\$(65)}
or

\section*{PRINT ASC("A")}

Virtually every Atari BASIC book (even Atari's own) shows the
character represented by each ATASCII code. You can also run Program 1 below to display each character and its code. (Press CTRL-1 to pause and continue the display.)

\section*{Screen Codes}

The second character code found in your Atari is the keyboard code. The keyboard code for any character is actually the value read from a hardware register in memory when the key for that character on the keyboard is pressed. Program 2 below lets you find the keyboard code for any character. Just for fun, try some of the keys or key combinations which don't normally produce characters, such as CTRL-SHIFT-

CAPS）．Neat，huh？
Finally：screen codes．This term refers to the byte value you must store in memory to display the de－ sired character on the screen． ＂What？＂you ask，＂How do those differ from the ATASCII codes？＂ After all，to put the string BANANA PICKLE PUDDING on the screen， all it takes is a simple BASIC statement：

\section*{PRINT＂BANANA PICKLE PUDDING＂}

And besides，aren＇t the charac－ ters in quotes supposed to be ATASCII codes？Good questions． Now for some complicated answers．

Actually，if the original Atari designers had thought just a little harder and added just a few more logic gates to the thousands already in the ANTIC and GTIA chips， ATASCII and screen codes could have been one and the same．It＇s similar to the mistake of making ATASCII incompatible with ASCII． Sigh．But we＇re stuck with what we＇ve got，so let＇s figure out how it works．

For starters，consider GRAPH－ ICS 1 and GRAPHICS 2，the large－ size character modes．You may have noticed that in either of these modes you can display only 64 dif－ ferent characters on the screen． Now，if you recall last month＇s demo programs，note that we can specify the base address of the char－ acter set．That is，we can tell ANTIC where the character set starts by changing the contents of memory location 756 （which is actually a shadow register of the hardware lo－ cation which does the work－see Mapping the Atari for more on this）．

In a sense，the ANTIC chip is fairly simplistic．When it finds a byte in memory which is supposed to represent a character on the screen，it simply adds the value of that byte（multiplied times eight， because there are eight bytes in the displayable form of a character）to the character set base address．This points to the memory address for that particular character．Ex－ cept．．．well，let＇s get to that in a moment．

\section*{Exception To The Rule}

Because we want GRAPHICS 1 and 2 （with their limited sets of 64 dif－ ferent characters）to display num－
bers and uppercase letters（omitting lowercase letters and graphics），for these two modes it makes sense that the character set starts with the dot representation of the space character and ends with the under－ line－codes 32 through 95， respectively．

But why are these 64 charac－ ters the only ones available in GRAPHICS 1 or 2？Because the up－ per two bits of a screen byte in these modes are interpreted as color information，not as part of the char－ acter（see the modification to Pro－ gram 3 below）．So only the lower six bits choose a character from the character set．Six bits can represent only 64 possible combinations， which is why these modes can dis－ play only 64 characters．Bit pattern 000000 becomes a space， 100101 is an \(E\) ，and 111111 becomes an un－ derline，and so on．

When you use GRAPHICS 0 （normal text），however，there is a strange side effect．In this mode， only the single upper bit is the color bit（actually，it＇s the inverse video bit）．This leaves 7 bits to represent a character，so we can have values from 0 to 127 decimal（ 0000000 to 1111111 binary，\(\$ 00\) to \(\$ 7 \mathrm{~F}\) hex）． Again，this value－after being multiplied by eight－is added to the value of the character set base address．But which numbers in that 0 to 127 range represent which characters？

Well，we already know what the first 64 characters are－since the Atari＇s hardware limitations dictate that they must be the same as in modes 1 and 2 ．So the next 64 are the other characters．Program 3 illustrates how the ATASCII char－ acter set is linked to the screen set． Note how all the characters are pre－ sented twice，once in screen code （i．e．，character ROM）order and once in ATASCII order．For some additional fun and info on modes 1 and 2，change line 10 to GRAPH－ ICS 1．（Do not change it to GRAPH－ ICS 2 unless you put a STOP in line 65 after the first FOR－NEXT loop．） Do you see what I mean about the upper two bits being color information？

Now you know why there are three different character codes used in your computer．How can you take advantage of this information？

Well，if you combine this knowl－ edge with the programs I presented last month，you could invent your own character set and design a word processor for some foreign language．（If you come up with a good Cyrillic character set，let me know．）

Actually，if you own an XL or XE machine，you have a second character set already built in．Just add this line to Program 3：
20 POKE 756，204
This tells the operating system and ANTIC that the base of the character set is at \＄CCOO，which is where the international character set resides．Someday you might find some use for these characters． How will you know until you try？
For instructions on entering these listings， please refer to＂COMPUTEI＇s Guide to Typing In Programs＂in this issue of COMPUTEI．

\title{
Cutting Strings Without Scissors
}

Now that we've covered the fundamentals of creating string variables over the past few columns, we can start exploring some of the more powerful string manipulations available in BASIC. Practically all BASIC languages have commands and functions for slicing strings of characters into smaller pieces, pasting two or more strings together to make longer strings, extracting certain sections from within strings, and inserting or replacing portions of strings. Some BASICs even have commands for rapidly searching through strings to find certain sequences of characters.

Since it may not be apparent why you'd want to do any of these things in your own programs, we'll show some common examples for each technique as we go along. In general, these functions give your programs the power to manipulate strings of characters for sorting, screen formatting, printing, storing and retrieving information, and other text-oriented operations.

\section*{Slicing Up Strings}

Microsoft-style BASICs-such as those included with Commodore, Apple, IBM, Atari ST, and Amiga computers-generally have three functions for extracting shorter strings from longer strings: LEFT\$, RIGHT\$, and MID\$ (pronounced "left-string," "right-string," and "mid-string"). TI BASIC has only one string function, SEG\$, which is very similar to MID\$. Atari BASIC, found on the \(400 / 800, \mathrm{XL}\), and XE computers, handles string manipulations quite differently, as we'll see next month.

LEFT\$ and RIGHT\$ are easy to visualize: They extract characters from the leftmost and rightmost sections of a character string, respectively. You simply follow the keyword with the string variable you're extracting from and the number of characters you want to
extract. For example:
10 A \(\mathbf{\$ =}=\) "GEORGE WASHINGTON CARVER"
20 PRINT As
\(30 \mathrm{~B}=\) LEFT \((\mathrm{A} \$, 6)\)
40 PRINT BS
\(50 \mathrm{~B} \$=\operatorname{RIGHT} \$(\mathrm{~A} \$, 6)\)
60 PRINT B \(\$\)
70 PRINT AS
When you type RUN, you should see this on the screen:

\section*{GEORGE WASHINGTON CARVER} GEORGE

\section*{CARVER}

\section*{GEORGE WASHINGTON CARVER}

To see how LEFT\$ works, look at the statement \(\mathrm{B} \$=\operatorname{LEFT} \$(\mathrm{~A} \$, 6)\) in line 30 . It grabs the leftmost six characters of A\$-GEORGE-and stores them in \(\mathrm{B} \$\). Line 40 confirms this by printing \(\mathrm{B} \$\). To extract the phrase GEORGE WASHINGTON from A\$, we could change line 30 to read \(\mathrm{B} \$=\mathrm{LEFT} \$(\mathrm{~A} \$, 17)\)-keeping in mind that spaces count as characters, just like letters, numbers, and symbols. (Of course, you can use your own variable names for A\$ and \(B \$\) as long as you stick to this basic format.)

RIGHT\$ is the opposite of LEFT\$: It extracts the rightmost number of characters in A\$ that you specify in the RIGHT\$ statement. If you change line 50 to read \(\mathrm{B} \$=\) RIGHT\$(A\$,17), the result is WASHINGTON CARVER.

Line 70 shows that \(A \$\) remains intact after sections of it have been extracted with the LEFT\$ and RIGHT\$ functions. LEFT\$ and RIGHT\$ actually copy sections of the string into \(\mathrm{B} \$\), rather than cutting the sections out.

\section*{Putting Lefty To Work}

If you specify a value in a LEFT\$ or RIGHT\$ statement that is greater than the length of the string-in this case, say, \(\mathrm{B} \$=\operatorname{LEFT} \$(\mathrm{~A} \$, 35)\) most BASICs return all of \(A \$\) in \(B \$\), the equivalent of \(B \$=A \$\). This can happen in a program when you're unsure about the current length of

A\$, or if you're using a variable for the number parameter in a LEFT\$ or RIGHT\$ statement and the variable somehow is increased beyond the length of \(\mathrm{A} \$\). If you specify a zero for this number-as in \(\mathrm{B} \$=\) RIGHT\$(A\$,0)-most BASICs return a null (empty) string.

If the number you specify in the LEFT\$ or RIGHT\$ statement is greater than 255 , you'll probably get an error. Most Microsoft BASICs don't allow strings longer than 255 characters, so any reference to numbers greater than 255 in stringmanipulation statements is invalid. Exceptions are the latest and most advanced Microsoft BASICs, such as Macintosh Microsoft BASIC and Amiga BASIC. They allow strings up to 32,767 characters long.

Of the two functions, LEFT\$ is probably used more often than RIGHT\$. One practical application of LEFT\$ is to truncate user input to a predetermined length. For instance, let's say you're writing a program that asks for the user's name. At some point your program prints the name on the screen, but you want to limit the name to ten characters to keep from messing up your screen formatting. The solution is a line such as INPUT MYNAME \(:\) MYNAME \(=\) LEFT \(\$\) (MYNAME \(\$, 10\) ). Note that in this case, the original content of MYNAME\$ is lost, because the LEFT\$ function stores the leftmost ten characters back into MYNAME\$.

Here's another application for LEFT\$: Suppose your program asks the user a yes or no question. You can evaluate the answer with a line such as INPUT ANSWER\$:IF LEFT\$ (ANSWER\$,1)="Y" THEN GOTO 1000 (assuming that line 1000 is the beginning of your "Yes" routine). That way, your program responds correctly whether the user types Y , YES, YEAH, YEP, YES SIR, or even YOU BET.

\section*{Humanizing The User Interface, Part 1}

Computers should be easy to use. Somehow this seems an obvious requirement for a product, yet many computer users are frustrated at the cumbersome nature of the programs they use day in and day out.

In previous columns, I've argued the case that computers should be transparent to their us-ers-that the computer should disappear into the background, freeing the user to interact directly with the application. A key to transparent computing is the user interfacethe vehicle through which the user interacts with the computer. The user interface has three compo-nents-input, output, and content.

Input generally involves the communication of physical motion from the user to the computer, signaling the computer to perform various activities. Typing on a keyboard, speaking into a microphone, or drawing a line with a finger on a touch tablet are all ways of using physical movement to convey information to a computer.

Output consists of messages communicated from the computer to the user's senses. The most often-used sense is vision-usually the screen display.

Content is the purpose of the computer activity-the management of text, the computation of spreadsheets, or the creation of graphic images, to name just a few. Although input flows from the user to the computer, and output goes from the computer to the user, the communication of content is purely inferential. In other words, the user has an internal model of what the computer program is doing, or how it is doing its task. To use a program successfully, it's not important if the user's model of what is happening is accurate. All that's important is if the model is consistent with the program's behavior.

\section*{Joy Or Pain}

When we're working with a program that has a well-balanced user interface, computing is a joy. When the user interface is bad, we may think that computing just isn't worth the effort.

Fortunately there are a few good programs available that show how easy computers can be to use. Most users of The Print Shop (from Brøderbund) would agree that this product is wonderfully easy to use. Many people probably haven't read the instruction manual. This product also has good input and output interfaces that step the user through the creation of customized greeting cards, posters, banners, calendars, etc. This product is one of the top sellers of all time, so the role of a good user interface cannot be underestimated.

Quite often, software designers try to make their products easy to use by designing them to work with a modern input device like a mouse or touch tablet. Unfortunately, this isn't enough. For a computer application to appear transparent, the input, output, and content of the system must be meshed to create a combined ambience that is both natural to the user and appropriate to the task at hand. For example, any attempt to design input devices independently of the applications that use them is risky at best. A
program that lets numbers be entered with a joystick may be appropriate for a game in which the joystick is used to select the number of players, but it is clearly the wrong approach for a financial analysis package that requires almost constant entry and update of numbers.

One reason I invented the KoalaPad was to make computers easier to use. Yet input devices like the KoalaPad are not enough by themselves. They can play an important role only when their use is a complementary part of the design of the whole product. This is why some people are frustrated by the Macintosh-not all Mac software is easy to use. It's true that this computer (and the Amiga) is capable of supporting tremendously powerful and easy-to-use software; but it's also true that many programs fall short in this important area.

It's hard to design a good user interface. Millions of dollars went into the research at Xerox that led to the desktop metaphor-the use of windows and pop-up menus that are now becoming commonplace. It took a heavy investment to bring the KoalaPad and Muppet Learning Keys to market. The cost of developing a good program for a personal computer can easily exceed \(\$ 100,000\). (Remember this the next time you think software costs too much!)

As difficult as this task may seem, those of us involved with computer software development owe it to our customers to make ease-of-use our top priority. The market slump of 1984 and 1985 showed that the public is unwilling to blindly accept everything thrown its way.

Next month we'll explore one model of human behavior that provides valuable clues in the search for the best user interfaces.

\section*{Snowflakes, Quilts, And Stained Glass Windows}

Recently I reviewed the new Amiga from Commodore on public TV's Educational Computing. Afterward, I hoped to have a few days to play with the machine before returning it. But I hadn't reckoned with my kids.

They were hooked on the Amiga's mouse, windows, and brilliant colors the first time I turned on the computer. They played with it constantly. The only time I got on the machine was after their bedtime.

My children's favorite program was Electronic Arts' Deluxe Paint. It is the most spectacular microcomputer paint program I have ever seen. With its animated, cycling colors and its dozens of drawing and painting tools, it even surpasses the MacPaint program on the Macintosh. It is so seductive and so much fun to use that it qualifies as "computer popcorn" (see my column on "Computer Popcorn," COMPUTE!, January 1984). Once you start using it, it's almost impossible to stop.

Like my children, I quickly fell in love with the program. But I still had a nagging doubt. Computer popcorn is scrumptious. But is it also nutritious? How could my children and I use the program to feed our minds and imaginations? Could the program teach us to be artists?

\section*{Just A Doodler}

So many computer art programs are of the easy-draw variety, like easycook microwave ovens and easyplay organs. They get you started drawing, playing, and having fun in no time at all. Then, bonk!, you bump into the limitations of your own skills, abilities, and imagination. You've become a super doodler, but you aren't any closer to making professional drawings, pictures, or art. That's because creativity programs, in general, are tools, not teachers. They are enormously enticing tools, but they can never
replace a certain amount of training or skill.

Like many people whose artistic aspirations far exceed their abilities, I found this situation extremely frustrating. And I wondered how my children could acquire the skills to use this program properly. I couldn't teach them the skills, and neither could the program.

Then, suddenly, a solution appeared. One night my six-year-old son Eric was scribbling away on the Amiga with Deluxe Paint. "Do you like my picture?" he said, turning toward us. My wife and I looked up. We were astounded. From across the room, Eric's glowing picture resembled a stained-glass window. It could have adorned a medieval cathedral. It was beautiful!

Later, as I was falling asleep, I realized Eric had helped me stumble onto a way out of my dilemma. What we needed were imagesimages drawn from the real world and from works of art. We could study these images, copy them, and use them as inspiration to build new pictures of our own.

\section*{The Butterfly Maiden}

The next day I went to the local library and checked out books on embroidery, quilting, needlepoint, and nature. The books were filled with images-colorful pictures of the diverse designs and patterns that man and nature can devise. These were to be our teachers.

When I showed these images to my children, I concentrated on patterns and shapes that were symmetrical and geometric. Eric and my daughter Catie could draw these images effortlessly with the tools in Deluxe Paint. Catie especially liked the totem-pole faces on blankets woven by the Chilkat Indians of the Pacific Northwest; the brilliant colors and intricate geometric patterns found in nine-
teenth-century American pieced quilts; and pictures of the Butterfly Maiden, a Hopi kachina doll from northeastern Arizona.

I liked a tapestry, Nightsun, by the German artist Dirk Holger. Eric liked the Resurrection angels, saints, and serpents he found on stained-glass windows from South Africa, the French Loire, and Dublin, Ireland.

As we tried to copy these pictures, and those of Persian lions, helix-shelled snails, and the swirling atmosphere of Jupiter, we found that some images were easier to work with than others. Anything made with needlework, stitching, or embroidery was especially nice because the graph-paper patterns resembled pixels on the computer screen. Pure colors were easier than complex shadings and color blends. The blocky nature of many images was easy to reproduce on the computer, and big patterns made by endlessly repeating little patterns were easy to build using copy and paintbrush commands.

The next day, we went outdoors to look for images on our own. Our field trip turned up all sorts of new shapes: water spurting from the garden hose, wedding cakes at a local bakery, pine cones, and wildflowers. We carried many of these objects to the computer and tried copying their basic patterns. And at night we went back outdoors and looked up at the stars. When we grew cold, we came inside and drew dot-to-dot constellations.

We had found a solution to our problem. We had taken a first step toward becoming computer artists. And we did it by feeding our imagination fresh images, and by studying and copying these images to uncover their underlying patterns and designs.

\section*{Games Modem People Play}

When most people think about telecomputing, the first things that probably come to mind will be downloading public domain programs from electronic bulletin boards, retrieving stock quotes and financial information from commercial information services, or communicating with other hobbyists via Special Interest Groups (SIGs). Modems are often viewed as strictly utilitarian pieces of computer gear.

But there is a lighter side to telecomputing-multiple-player telegaming.

The first multiplayer telecomputing game I can recall involved a group of five or six people who were logged onto an online conferencing service playing Dungeons and Dragons. Players in California, Illinois, and New York were exploring the stygian depths of underground catacombs created by a Dungeon Master running the whole show from the keyboard of his Apple II in Austin, Texas.

The CompuServe Information Service was one of the pioneers in developing multiplayer online games. CompuServe currently offers a half-dozen or so such diversions to its subscribers. The blast-and-burn crowd can choose among multiple flavors of interstellar conflict: SpaceWars, MegaWars I, and MegaWars III. These games vary in both depth of play and the number of players who may simultaneously participate. MegaWars III is the clear heavyweight of the group. It has multiple game phases, including violent battle and economic warfare, and up to a hundred players can be pounding away at their keyboards at once.

Those with more pedestrian tastes may opt for a game of multiplayer blackjack, trading quips with the dealer and other players as electronic gambling chips trade hands.

\section*{Wheel Of Misfortune}

Not all attempts at multiuser games are smash hits. CompuServe's latest creation is You Guessed It!, a TVstyle quiz game in which players form teams and take turns attempting to answer questions while ignoring incredibly bad jokes delivered by an eerily obnoxious electronic master of ceremonies. The winners garner points that may be used to purchase gifts offered by sponsors, whose commercials regularly interrupt the game.

I tried You Guessed It! for about two hours, racking up what I thought was a respectable number of points. Then I eagerly issued the command that would transfer me to the "prize room" where players can trade points for their heart's desire. But the only prize I qualified for was a bumper sticker that advertised one of the You Guessed It! sponsors. To be fair, it did appear that if I played for another hour or two I could lay my hands on a baseball cap which sported (you guessed it) another advertiser's logo.

One of the more interesting experiments in telegaming that I've seen is a moderately obscure program called COMM-BAT, marketed by Adventure International. Some friends and I purchased copies of COMM-BAT for our Atari 800s back in early 1981 when 300 bits-persecond (bps) modems were still hot stuff for home use.

COMM-BAT lets two computers hook up over phone lines and presents each player with a battlefield map. The adversaries send tanks armed with rockets and lasers scurrying about in search of the enemy's base. When a player's base is destroyed, the game ends. The programs on both ends of the telecomputing link communicate with each other, updating the current battle information displayed on the
screens. Players can also send insults and ultimatums to each other during the game.

\section*{A Reunion Battle}

COMM-BAT does have its limitations. The character graphics are crude, but intentionally so. Versions of COMM-BAT were written for TRS-80, Apple, and Atari computers, and owners of these different systems could play COMM-BAT with each other and see identical displays on their screens. The biggest drawback was that the game progressed rather slowly due to the 300 bps modems.

Just for grins I pulled out my old copy of COMM-BAT and called one of my ex-buddies, now a resident of Denver, Colorado and a fellow user of GTE's PC Pursuit service (see "Telecomputing Today," December 1985). We cranked up our Ataris (now equipped with 1200 bps modems), linked up via PC Pursuit, and had a jolly old transcontinental time blasting the daylights out of each other. The extra speed of the 1200 bps modems and a noise-free connection transformed a mildly interesting game into good, clean Ramboesque fun. Out of curiosity, I called Adventure International and found that \(C O M M-B A T\) is still available. The \(\$ 49.95\) price gets you all three versions of the program.

I'd like to hear about any other commercial or public domain telecomputing games that you may have encountered. I seem to recall some implementations of chess and Battleship having been done in the past. I'll compile a list and publish the results in a future issue. Contact Levitan on The Source (TCT987), CompuServe \((70675,463)\), or Delphi (ARLANL).

\title{
The Ultimate Entertainment Center
}

Picture yourself in front of a 26 inch color monitor-shoes off, feet up, remote control in hand. But this is not just any remote control. This is a special remote unit that controls all of the components in your entertainment/computing system.

You push the TV button and bring up World News Tonight on the monitor: Peter Jennings reports that the stock market has soared to new highs. As he fades into a commercial, you decide to call Dow Jones News/Retrieval to see how your own stocks did. But first, you push the compact disc button to fill the room with a Beethoven symphony so real that you wonder where the orchestra is hiding. Then you press the VID2 key to put the computer video on the screen. You reach for the PCjr's wireless keyboard and start the appropriate communications program; then you press TV to return to the news while the computer retrieves the quotes.

At the next break, you display the Dow Jones results onscreen with the VID2 key. After the newscast, you press the VCR STOP, REWIND, and PLAY keys to view the " \(\mathrm{M}^{*} \mathrm{~A}^{*} \mathrm{~S}^{*} \mathrm{H}^{\prime \prime}\) rerun you've been taping from an independent station. But first, you check the progress of the cassette tape you've been recording from an FM stereo broadcast.

This isn't a pipe dream-this is RCA's Dimensia. Billed as intelligent audio/video, it integrates numerous components into a single system commanded from a single remote control. The heart of the system is a 26 -inch stereo monitor/ receiver. Once you acquire the monitor, you can add other components according to your needs and budget. Current Dimensia components are an AM/FM receiver/ amplifier, a compact audio disc player, a cassette tape recorder, two phonographs, a graphic equalizer, and several models of stereo VHS video recorders.

\section*{Connection Options}

RCA designed the Dimensia system so you can also connect nonDimensia components, including home computers. The PCjr, with its wireless keyboard, is a particularly good choice; it can be connected in three ways. Like most home computers and videogame machines, the PCjr can be hooked up to a TV's antenna terminals with an RF modulator. Since the Dimensia system allows multiple antennas-selected by remote control-you can switch between the PCjr's screen, cable service, and a satellite dish.

The PCjr also has a composite video output that can be connected to one of the monitor's three video input jacks. The PREVIOUS CHANNEL key lets you instantly switch between a TV program and the computer screen, so you can watch Dynasty and play King's Quest at the same time.

A third connection option is the Dimensia's RGB direct-drive video input. Although the Dimensia's RGB connectors aren't compatible with the PCjr's RGB plug, the signals are compatible. Radio Shack sells a four-conductor, colorcoded patch cable that can be modified by anyone handy with a soldering iron to make the connection.

For everything but text, the Dimensia's composite video is as clear as the RGB mode, and it has an added advantage: You can record its output with a video cassette recorder. This means you can run programs on the PCjr and record the results on the VCR, which is perfect for putting titles on your home videos. You can also dub stereo audio from a compact disc player, the AM/FM tuner, the cassette recorder, or the phonograph.

\section*{A Piqued PCjr}

Since both the Dimensia and the PCjr keyboard use an infrared re-
mote control, there is the possibility of conflict. I couldn't find any button on the Dimensia's 52 -key remote controller that the PCjr would recognize, but the computer was well aware that strange infrared signals were reaching its sensor. It squealed like a perturbed pig every time I used the Dimensia remote. This is easily and permanently solved by amputating Junior's little beeper-something I had intended to do for months anyway.

There's another annoying aspect of the PCjr you may want to fix, even if you don't have the Dimensia monitor. The joystick is not a wireless device and the cable that connects it to the computer is too short to reach across the room. Once again, it's Radio Shack to the rescue with its ten-foot joystick extension cord. Of course, this cord was designed for Tandy computers and the connections are not compatible with the PCjr's unusual plugs, so it's back to the soldering iron. Simply chop the joystick cable about eight inches from where it connects to the computer and solder a sub-D nine-pin connector (also available at Radio Shack) on each end, being careful to keep the pin numbers and wire colors consistent. It works perfectly.

The complete Dimensia system with all the components can cost as much as \(\$ 5,000\)-but don't hesitate to haggle. The more components you buy, the better deal you can get.

Besides its flexibility, the Dimensia also may be the world's most user-friendly entertainment center. Although not documented in the manuals and unknown to sales people, the monitor displays a help screen across the bottom of the picture when you press AUX 00. Drop by a dealer and try it.

\section*{IF-THEN Statements}

IF-THEN statements are conditional transfer commands that make it seem as if computers can think. IF a specified condition is true, THEN the program skips to a certain line number elsewhere in the program; otherwise, the program simply continues to the next line as usual. TI BASIC also allows an ELSE statement as part of IF-THEN. It takes this form:

\section*{IF condition THEN line1 ELSE line 2}

IF the condition is true, THEN the computer goes to line1, or ELSE the computer goes to line2. If the optional ELSE is omitted, control merely passes to the following line. Here's a common example:
200 IF SCORE \(=10\) THEN 900
210 PRINT SCORE
This statement says that if the value of the variable SCORE is equal to 10 , then the program should continue at line 900. Otherwise, the program continues to the next line and prints the score.

You can use the other relational operators to define conditions in IF-THEN statements, too:

\section*{300 IF A<B THEN 700}

400 IF X>Y THEN 200 ELSE 580
500 IF J<>8 THEN 800
In each case, the computer evaluates the condition-the expression between the words IF and THEN. If the expression is true, it has the value of -1 . If the expression is false, it has the value of zero. Therefore, a statement such as this is valid:

\section*{320 IF A THEN 400}

This doesn't look like the more common relational examples, but it implies that if A is equal to -1 , then the program goes to line 400 .

The condition may look more complex. If you keep in mind that true is -1 and false is zero, you can usually follow the logic. An example is:
150 IF \((\mathrm{A}=\mathrm{B})+\mathrm{C}\) THEN 200

The part within the parentheses \((A=B)\) is evaluated first. If \(A\) equals B , then the expression is -1 (true); if A does not equal B , the expression is zero (false). This value is then added to the value for C . If the result is -1 , the condition is true and control passes to line 200.

\section*{Simulating AND/OR}

Most other versions of BASIC allow the use of AND and OR in IFTHEN expressions. TI BASIC does not, but we can translate. Again, keep in mind that -1 indicates true.

Suppose we want to test the conditions \(\mathrm{A}=\mathrm{B}\) and \(\mathrm{C}=\mathrm{D}\). If both are true (IF \(A=B\) AND \(C=D\) ), then we want the program to continue at line 700. Here's one way to do this: IF \((A=B)+(C=D)=-2\) THEN 700
If both conditions are true, each will yield -1 values, so the total will be -2 .

Here's an equivalent way to make this test:
IF \(-(\mathrm{A}=\mathrm{B})^{*}(\mathrm{C}=\mathrm{D})\) THEN 700
Notice that -1 times -1 is +1 , so the negative sign in front converts the whole expression to -1 for true.

The word OR is used when one condition OR the other condition is true, but not both:
IF \((X<Y)\) OR \((X>Z)\) THEN 300
This can be translated to TI BASIC like this:

\section*{IF \((\mathbf{X}<\mathrm{Y})+(\mathrm{X}>\mathrm{Z})\) THEN 300}

Program control transfers to line 300 only if the expression evaluates to -1 . This happens if only one of the conditions in parentheses is true (and thus -1 ) and the other is false (equal to zero).

Even more complex IF-THEN statements are possible by considering different combinations of + and * in evaluating conditions. Suppose after a CALL KEY statement the user may press either ENTER or any of the number keys. Here's the
easiest way to set up the logic:
200 CALL KEY( \(0, \mathrm{~K}, \mathrm{~S}\) )
210 IF K=13 THEN 500
220 IF \(\mathrm{K}<48\) THEN 200
230 IF K>57 THEN 200
Or you can combine the IF statements like this:
210 IF \((\mathrm{K}<>13)+(\mathrm{K}<48)+(\mathrm{K}>57)\) THEN 200

\section*{Algebra Drill}

The sample program this month is a simple drill for beginning algebra students who are learning to add signed numbers. This program illustrates the use of several kinds of IF-THEN statements.

Lines 200 and 230 show two ways to check the length of the numbers to see if a randomly chosen number is negative. If necessary, a plus sign is added to the number.

Lines 280 and 300 determine the answer depending on the value of SUM.

If the answer is zero, line 360 skips the procedure for choosing the plus or minus sign in the answer. If the student needs to choose the sign, line 420 makes sure he or she presses either the plus sign or the minus sign. All other keys are ignored. Line 490 then receives the number keys pressed.

Line 530 checks the student's answer and branches appropriately. Line 590 waits for the student to press the ENTER key before continuing.

If you wish to save typing effort, you can obtain a copy of "Adding Signed Numbers" by sending a blank cassette or disk, a stamped, self-addressed mailer, and \$3 to:
C. Regena
P.O. Box 1502

Cedar City, UT 84720

the forest with 12 friends, using the concepts of conjunction, disjunction, and negation to break the witch's spells.

The Enchanted Forest was written by Dr. Jerzy Cwirko-Godycki, author of more than 40 children's books. It's available for the 64 K Apple II+, IIe, and IIc; and the IBM PC and PCjr. The \(\$ 59\) list price includes a backup disk and teacher's guide.

Sunburst Communications, 39 Washington Avenue, Pleasantville, NY 10570. Circle Reader Service Number 204.

\section*{Beach-Head Sequel For Atari}

Beach-Head II, Access Software's sequel to the popular Beach-Head game, is now available in a version for the Atari \(400 / 800\), XL, and XE series with at least 48 K of RAM. Like its predecessor, Beach-Head II is a World War II era arcade game that is set on the beaches of Europe. The sequel has several new features including voice synthesis, multiple play screens and play levels, sound effects, and animation techniques.

Beach-Head II for Atari lists for \(\$ 39.95\). It has previously been released in versions for the Commodore 64/128 and Apple II series.

Access Software Inc., 2561 South 1560 West, Woods Cross, UT 84087.
Circle Reader Service Number 205.

\section*{Munching On The Apple}

Munchers and Troggles abound in the world of Word Munchers, an educational game for grades one through five from Minnesota Educational Computing Corporation. Players earn points by making their Munchers eat words with a particular vowel sound while avoiding the enemy Troggles. Teachers can determine which vowel sounds are used and can control the level of word difficulty. Approximately 1,700 words of varying difficulty are included.

Word Munchers runs on all Apple II computers with at least 64 K RAM; joystick is optional. Suggested retail price, \(\$ 49\).

Minnesota Educational Computing Corporation, 3490 Lexington Avenue North, St. Paul, MI 55112.
Circle Reader Service Number 206.

\section*{Commodore Chemistry}

Simon \& Schuster has released a Commodore 64 version of the Chem Lab educational program for ages nine through twelve. The program contains 50 chemistry experiments with three levels of difficulty. All experiments are simulations of real experiments with actual results. Players can work their way up from Lab Assistant to Nobel Prize Winner.

The computerized laboratory comes equipped with on-screen simulations of: two robot arms for handling chemicals and equipment, five different pieces of lab equipment, plus three Bunsen burners and separate dispensers for gases, liquids, and solids. The chemical reactions are animated and change color, glow, melt, boil, and explode. On-screen messages tell the players what has been created.

Chem Lab for the Commodore 64, with its 96 -page user's guide, sells for \(\$ 39.95\). Apple II and IBM PC/PCjr versions are also available.

Simon \& Schuster Computer Software, 1230 Avenue of the Americas, New York, NY 10020.
Circle Reader Service Number 207.

\section*{Gandalf The Sorcerer For 64}

A spellbound treasure is hidden in a castle surrounded by scaly tailed lizardmen. You, Gandalf the Sorcerer, must protect the treasure by using magic powers from a shining star. Such is the scenario of Gandalf the Sorcerer, Tymac's new adventure game for the Commodore 64. The game is for one player and requires a joystick. Threedimensional graphics are featured.

Suggested retail price is \(\$ 39.95\).
Tymac Controls Corporation, 127 Main Street, Franklin, NJ 07416.
Circle Reader Service Number 208.

The lizardmen ambush the castle in Gandalf the Sorcerer.

Paper Airplane Kit
Simon \& Schuster has released The Great International Paper Airplane Construction Kit, a set of paper airplane templates based on the bestselling book by the same name. The program contains over a dozen full-page paper airplane designs from biplanes to space shuttles. It also comes with a library of airplane graphics to embellish the airplanes with insignias, logos, windows, engines, pilots, and stewardesses. Also included is a step-by-step manual with instructions, suggestions, and a history of paper aviation.

The Great International Paper Airplane Construction Kit runs on the Ap-
ple II series with 64 K RAM (\$34.95); on the IBM PC, PC-XT, PC AT, and PCjr, with DOS 2.0 or higher and color/graphics card (\$34.95); on the Macintosh with 128 K RAM (\$39.95); and on the Commodore 64 or 128 (\$29.95).

Simon \& Schuster, 1230 Avenue of the Americas, New York, NY 10020.
Circle Reader Service Number 209.

\section*{New From Mindscape}

In Dick Francis' High Stakes, a new interactive text adventure from Mindscape, you are a wealthy English horse owner who must foil a sinister plot to cheat you. Based on the book by the popular mystery writer, Dick Francis, the game involves gambling and intrigue.

Also new from Mindscape are The American Challenge: A Sailing Simulation, which recreates the America's Cup sailing race, for one or two players; and James Bond 007 Goldfinger, an interactive text adventure involving travel, exotic weaponry, and the loves of the legendary 007.

Each game lists for \$39.95 and runs on the Apple II and IBM PC computers.

Mindscape Inc., 3444 Dundee Road, Northbrook, IL 60062.
Circle Reader Service Number 210.

\section*{Educational Programs For \\ Pre-School, High School}

Grover and Ernie from "Sesame Street" enliven two new educational games from CBS Learning Systems. Grover's Animal Adventures takes preschoolers into four different animal environments: the African Grasslands, the Atlantic Ocean, a North American forest, and a barnyard. Children select animated animals and objects and place them in the appropriate environment on land, in water, or in the sky. In Ernie's Big Splash, children help Ernie find his Rubber Duckie by building a pathway that leads from the Duckie's soap dish into Ernie's bathtub. Both games are for ages four to six; each lists for \(\$ 14.95\).

CBS has also released Mastering the ACT (American College Testing Assessment), a self-paced preparation course for high school students that was developed by the National Association of Secondary School Principals. The program features full-length simulated ACT pre- and post-tests which provide self-scoring and detailed error analysis. Development exercises cover English, math, social studies, and natural sciences. For the Commodore 64/128 (\$79.95), the Apple II series, and IBM PC and PCjr (\$99.95 each).

CBS Learning Systems, One Fawcett Place, Greenwich, CT 06836.
Circle Reader Service Number 211.

\title{
．\({ }^{-1}\) Machine Language Entry Program For Atari
}

Charles Brannon，Program Editor

MLX is a labor－saving utility that allows almost fail－safe entry of machine lan－ guage programs published in COMPUTE！． You need to know nothing about machine language to use MLX－it was designed for everyone．
＂MLX＂is a new way to enter long machine language（ML）programs with a minimum of fuss．MLX lets you enter the numbers from a special list that looks similar to BASIC DATA state－ ments．It checks your typing on a line－ by－line basis．It won＇t let you enter illegal characters when you should be typing numbers．It won＇t let you enter numbers greater than 255 （forbidden in ML）．It won＇t let you enter the wrong numbers on the wrong line．In addition， MLX creates a ready－to－use tape or disk file．

\section*{Using MLX}

Type in and save MLX（you＇ll want to use it in the future）．When you＇re ready to type in an ML program，run MLX． MLX asks you for three numbers：the starting address，the ending address， and the run／init address．These num－ bers are given in the article accompany－ ing the ML program presented in MLX format．You must also choose one of three options for saving the file：as a boot tape，as lisk binary file，or as boot disk．The article with the ML program should specify which formats may be used．

When you run MLX，you＇ll see a prompt corresponding to the starting address．The prompt is the current line you are entering from the listing．It increases by six each time you enter a line．That＇s because each line has seven numbers－six actual data numbers plus a checksum number．The checksum verifies that you typed the previous six numbers correctly．If you enter any of the six numbers wrong，or enter the checksum wrong，the computer rings a buzzer and prompts you to reenter the line．If you enter it correctly，a bell tone sounds and you continue to the next line．

MLX accepts only numbers as in－ put．If you rnake a typing error，press the DEL／BACK SPACE；the entire number is deleted．You can press it as many times as necessary back to the start of the line．If you enter three－digit numbers as listed，the computer auto－ matically prints the comma and goes on
to accept the next number．If you enter fewer than three digits，you can press the comma key，the space bar，or the RETURN key to advance to the next number．The checksum automatically appears in inverse video for emphasis．

\section*{MLX Commands}

When you finish typing an ML listing （assuming you type it all in one ses－ sion），you can then save the completed program on tape or disk．Follow the screen instructions．If you get any errors while saving，you probably have a bad disk，or the disk is full，or you＇ve made a typo when entering the MLX program itself．

You don＇t have to enter the whole ML program in one sitting．MLX lets you enter as much as you want，save it， and then reload the file from tape or disk later．MLX recognizes these commands：

\section*{CTRL－S Save \\ CTRL－L Load \\ CTRL－N New Address \\ CTRL－D Display}

To issue a command，hold down the CTRL key（CONTROL on the XL models）and press the indicated key． When you enter a command，MLX jumps out of the line you＇ve been typ－ ing，so we recommend you do it at a new prompt．Use the Save command （CTRL－S）to save what you＇ve been working on．It will save on tape or disk， as if you＇ve finished，but the tape or disk won＇t work，of course，until you finish the typing．Remember to make a note of what address you stop at．The next time you run MLX，answer all the prompts as you did before－regardless of where you stopped typing－then in－ sert the disk or tape．When you get to the line number prompt，press CTRL－L to reload the partly completed file into memory．Then use the New Address command to resume typing．

To use the New Address com－ mand，press CTRL－N and enter the ad－ dress where you previously stopped． The prompt will change，and you can then continue typing．Always enter a New Address that matches up with one of the line numbers in the MLX－format listing，or else the checksum won＇t work．The Display command lets you display a section of your typing．After you press CTRL－D，enter two addresses within the line number range of the listing．You can break out of the listing
display and return to the prompt by pressing any key．

\section*{Atarl MLX：Machine Language Entry}

For instructions on entering this listing，please refer to＂COMPUTEI＇s Guide to Typing In
Programs＂in this issue of COMPUTEI．

\title{
COMPUTEI＇s Guide To Typing In Programs
}

Computers are precise－type the pro－ gram exactly as listed，including neces－ sary punctuation and symbols，except for special characters noted below．We have implemented a special listing con－ vention as well as a program to check your typing－＂Automatic Proofreader．

Commodore，Apple，and Atari programs can contain some hard－to－ read special characters，so we have a listing system that indicates these con－ trol characters．You will find these Commodore and Atari characters in curly braces；do not type the braces．For example，\｛CLEAR\} or \(\{C L R\}\) instructs you to insert the symbol which clears the screen on the Atari or Commodore machines．For Commodore，Apple，and Atari，a symbol by itself within curly braces is usually a control key or graph－ ics key．If you see \(\{A\}\) ，hold down the CONTROL key and press A．This will produce a reverse video character on the Commodore（in quote mode），a graphics character on the Atari，and an invisible control character on the Ap－ ple．Graphics characters entered with the Commodore logo key are enclosed in a special bracket：［ \(<A>\) ］．In this case， you would hold down the Commodore logo key as you type A．Our Commo－ dore listings are in uppercase，so shifted symbols are underlined．A graphics heart symbol（SHIFT－S）would be listed as S．One exception is \｛SHIFT－ SPACE \}. When you see this, hold down SHIFT and press the space bar．If a number precedes a symbol，such as \(\{5\) RIGHT \(\}\) ，\(\{6 \mathrm{~S}\}\) ，or \([<8 \mathrm{Q}>]\) ，you would enter five cursor rights，six shifted S＇s， or eight Commodore－Q＇s．On the Atari， inverse characters（white on black） should be entered with the Atari logo key．

Any more than two spaces will be listed．For example，\(\{6\) SPACES \(\}\) means press the space bar six times．Our list－ ings never leave a space at the end of a line，instead moving it to the next print－ ed line as \｛SPACE ．

\section*{The Automatic Proofreader}

This month，we are featuring a com－ pletely new Proofreader for the Com－ modore 64，128，VIC，Plus／4，and 16. Please refer to＂The New Automatic Proofreader for Commodore＂article elsewhere in this issue for more infor－ mation．Type in the appropriate pro－ gram listed below，then save it for future use．On the Atari，run the Proof－ reader to activate it，then enter NEW to erase the BASIC loader（the Proofread－ er remains active in memory as a ma－ chine language program）．Pressing SYSTEM RESET deactivates the Proof－ reader．Use PRINT USR（1536）to reen－ able the Atari Proofreader．The Apple Proofreader erases the BASIC portion of itself after you RUN it，leaving only the machine language portion in mem－ ory．It works with either DOS 3.3 or ProDOS．Disable the Apple Proofread－ er by pressing CTRL－RESET before running another BASIC program．The IBM Proofreader is a BASIC program that simulates the IBM BASIC line edi－ tor，letting you enter，edit，list，save，and load programs that you type．Type RUN to activate．

Once the Proofreader is active，try typing in a line．As soon as you press RETURN，a hexadecimal number（on the Apple）or a pair of letters（on the Atari or IBM）appears．The number or pair of letters is called a checksum．

Compare the value provided by the Proofreader with the checksum printed in the program listing in the magazine．In Commodore listings，the checksum is set off from the rest of the line with rem．This prevents a syntax error if the checksum is typed in，but the REM statements and checksums need not be typed in．

In Atari，Apple，and IBM listings， the checksum is given to the left of each line number．Just type in the program，a line at a time（without the printed checksum）and compare the check－ sums．If they match，go on to the next line．If not，check your typing：You＇ve made a mistake．On the Atari and Ap－ ple Proofreaders，spaces are not count－ ed as part of the checksum，so be sure you type the right number of spaces between quote marks．The Atari Proof－ reader does not check to see that you＇ve typed the characters in the right order， so if characters are transposed，the checksum stil matches the listing．Be－ cause of the checksum method used，do not use abbreviations，such as ？for PRINT．The IBM Proofreader is the pickiest of all；it will detect errors in spacing and transposition．Be sure to leave Caps Lock on，except when typ－ ing lowercase characters．

IBM Proofreader Commands
Since the IBM Proofreader（Program 2） replaces the computer＇s normal BASIC line editor，it has to include many of the direct－mode IBM BASIC commands． The syntax is identical to IBM BASIC． Commands simulated are LIST，LLIST， NEW，FILES，SAVE，and LOAD．When listing your program，press any key（ex－ cept Ctrl－Break）to stop the listing．If you enter NEW，the Proofreader will prompt you to press \(Y\) to be especially sure you mean yes．

Two new commands are BASIC and CHECK．BASIC exits the Proof－ reader back to IBM BASIC，leaving the Proofreader in memory．CHECK works just like LIST，but shows the checksums along with the listing．After you have typed in a program，save it to disk． Then exit the Proofreader with the BASIC command，and load the pro－ gram into the normal BASIC environ－ ment（this will replace the Proofreader in memory）．You can now run the pro－ gram，but you may want to resave it to disk．This will shorten it on disk and make it load faster，but it can no longer be edited with the Proofreader．If you want to convert a program to Proof－ reader format，save it to disk with SAVE ＂filename＂， A ．

\section*{SpeedScript Update}

There is an error in the correction to Apple SpeedScript from the＂Speed－ Script 3．0 Revisited＂article in the December 1985 issue（p．90）which causes the page number to repeat continuously when the \＃format－ ting command is used．In line 1C88 of the listing，the 9D should be a 9C．Load SpeedScript back into Ap－ ple＂MLX＂and enter the following replacement line：
1C88：AC E5 1E D0 9C AE E6 1E EC
After making the correction，be sure to use the MLX Save option to save a new copy of SpeedScript．

The item in the January 1986 ＂Reader＇s Feedback＂column（p． 10）that told how to make Commo－ dore 64 SpeedScript 3.0 default to disk for saving and loading had transposed digits in the middle POKE address．The line should have read：

POKE 4904，234：POKE 4905，169：POKE 4906，68
This modification works for all up－ dates of version 3 （3．0，3．1，or 3．2）．

\section*{Atari Solitaire}

The Atari listing for this game from the January 1986 issue（Program 2， p．48）has a typographical error in line 910．The third character in S\＄， which defines the card suits，should be \(\{\).\(\} instead of the apostrophe\) shown．CTRL－period is the dia－ mond graphic character．

\section*{Formatted Prinfouts For Commodore}

There are two errors in the DATA statements for this program from the January 1986 issue（p．99）．In line 540，the null string，＇＂＇，should come before the item＂BLACK＂ rather than after it．In line 640，the last item in the line should be＂\(\uparrow\)＂ rather than a null string．

\section*{Skyscape For IBM \＆Apple}

Certain combinations of date and time inputs cause syntax errors in the IBM and Apple versions of this astronomy program from the No－ vember 1985 issue（p．62）．To cor－ rect this，change \(C C<=0\) to \(C C\) \(<=1\) in line 2060 of the IBM ver－ sion（Program 3）and line 1770 of the Apple version（Program 4）．

\section*{Memo Diary}

The Commodore version of this calendar utility from the December 1985 issue（p．65）won＇t work with tape．Tape users should modify the OPEN statement in line 3170 as follows：

OPEN \(1,1+7^{*}\) D1，8＊D1 \(+1, \mathrm{FS}+\mathrm{G}\) ：
Author Jim Butterfield also recom－ mends that line 660 be replaced with 660 REM．With this change the calendar file will always be updated．

\author{
THE AMAZING VOICE MASTER \({ }^{\circledR}\)
}

\author{
Speech and Music Processor
}

Your computer can talk in your own
voice. Not a synthesizer but a true digitizer that records your natural voice quality-and in any language or accent. Words and phrases can be expanded without limit from disk.
And it will understand what you say. A real word recognizer for groups of 32 words or phrases with unlimited expansion from disk memory. Now you can have a two way conversation with your computer!
Easy for the beginning programmer with new BASIC commands. Machine language programs and memory locations for the more experienced software author.
Exciting Music Bonus lets you hum or whistle to write and perform. Notes literally scroll by as you hum! Your composition can be edited, saved, and printed out. You don't have to know one note from another in order to write and compose!
Based upon new technologies invented by covox. One low price buys you the complete system-even a voice controlled black-jack game! In addition, you will receive a subscription to COVOX NEWS, a periodic newsletter about speech technology, applications, new products, up-dates, and user contributions.
You will never find a better value for your computer.
ONLY \$89.95
includes all hardware and software.
For telephone demonstration or additional information, call (503) \(342-1271\). FREE audio demo tape and brochure available. Available from your dealer or by mail. When ordering by mail add \(\$ 4.00\) shipping and handling ( \(\$ 10.00\) for foreign, \(\$ 6.00\) Canada).

The Voice Master is available for the C64, C128, all Apple II's, and Atari 800, 800 XL and 130XE. Specify model when ordering.
