# HOW PEOPLE WITH COMMON InTERESTS FIND AN INTERESTING COMMON GROUND. 

## Presenting CompuServe Forums. Where people from all over get together, without even leaving home.

Now thanks to CompuServe Forums, computer owners are sharing common interests by talking to each other through their computer keyboards. Software users, computer enthusiasts, ham operators, french cooks, fire fighters, science fiction lovers and other special interest groups are already in touch, online.

Because when you subscribe to CompuServe, you're able to reach people who want to talk about the things you do. As many people as you like. For as long as you like. Whenever you wish. Join a conversation already in
progress or start one on your own. Ask questions. And get answers.

All it takes is a modem, most any personal computer and CompuServe.

Forum members across the country are as close as a local phone call.

You can go online with just a local call in most major metropolitan areas. And normal usage fees for weekday nights and weekends are just $10 ¢$ a minute

## Of special interest to all Forum

 participants is software that's FREE for the taking.Public domain software. For all sorts of activities, from games to business programs. And it's just as easy to copy a piece of software as it is to participate in a Forum.

## Become a CompuServe subscriber and

 get a $\$ 25$ Usage Credit to start you off.Becoming a subscriber is as easy as contacting your local computer dealer. Or you can call us and order direct. Suggested retail price is $\$ 39.95$.

And if you'd want more information about CompuServe, we'll be happy to send you a free brochure. Because with all that CompuServe offers-we think it's in your best interest.

# TAP THE POWER of the Commodore 128 

## By the author of Machine Language for Beginners and Second Book of Machine Language

## 128 Machine Language for Beginners <br> Richard Mansfield

One of the bestselling computer books ever has now been completely revised for the Commodore 128. Most commercial software is written in machine language because it's far faster and more versatile than BASIC. This new edition of Machine Language for Beginners is a step-by-step introduction to 8502 machine language programming on Commodore's 128 computer.

The book includes everything you need to learn to effectively program the 128: numerous programming examples, memory management tutorials; a complete description of the many Kernal routines and other new 128 features; numerous hints and programming techniques; and a dictionary of all major BASIC commands and their machine language equivalents. It also includes a high-speed, professional-quality, label-based assembler, optimized to take advantage of the speed and extra memory of the 128.
0-87455-033-5
\$16.95
Like the other top-quality books from COMPUTEI, 128 Machine Language for Beginners brings you ready-to-use information in a clear, lively style that makes learning easy and enjoyable, whether you are a beginner or an advanced computer user.

An optional disk is also available which includes the assembler and example programs in the book. The 128 LADS Disk is fully tested and ready to load on the Commodore 128. It costs only $\$ 12.95$ and saves you hours of typing time.

Order your copy of 128 Machine Language for Beginners and the LADS Disk today. Call toll free 1-800-346-6767 (in NY 1-212-887-8525) or mail your payment (plus $\$ 2.00$ shipping per book or disk) to COMPUTE! Books, P.O. Box 5038, F.D.R. Station, New York, NY 10150.

# \$10,000.00 Atari ST Programming Contest! 

First Prize \$5,000.00

Second Prize \$2,500.00

## Third Prize \$1,000.00

## Three Honorable Mentions \$500.00 each

COMPUTE! Publications, Inc. is looking for the very best original software for the Atari ST series computers. And to prove we're serious, we're offering a total of $\$ 10,000.00$ in prize money to the top six winners. That's $\$ 5,000.00$ for First Prize, $\$ 2,500.00$ for Second Prize, $\$ 1,000.00$ for Third Prize, and $\$ 500.00$ each for three Honorable Mentions. In addition, the winners will receive our standard royalties when their programs are published. And even if your program doesn't win a prize, you can still earn purchase fees and royalties if we accept your entry for publication.

Interested? If so, read these rules:

#### Abstract

1. Entries must be your original work, previously unpublished. All those whose programs are accepted will be required to affirm this in writing. 2. You can submit as many entries as you want, but we cannot consider programs which have been entered in other contests or submitted for publication elsewhere at the same time. 3. The deadline is October 1, 1986. All entries must be received at our offices by this date. Programs submitted after this date will still be considered for publication, but will not be entered in the contest. 4. Entries are allowed (and encouraged) in virtually all software categories: home and business applications, education, recreation, telecommunications, graphics, sound and music, utilities, and desk accessories. 5. Entries may be written in any programming language-including BASIC, Logo, C, machine language, Pascal, Modula-2, Forth, FORTRAN, and Prolog-as long as they meet two requirements. First, if you're using a compiled language, the compiled object or run-time code must be a selfstanding program that can be run by someone who doesn't own a copy of the language. (Exceptions are ST BASIC and Logo. Since these languages come with the ST, it can be assumed that everyone owns a copy.) Second, we must be able to legally distribute the program without incurring licensing fees or other obligations to the maker of the language. If you're not sure whether a certain language qualifies, contact its maker for clarification. 6. Entries must be submitted on a single- or double-sided $31 / 2$-inch ST disk with both the run-time code and source code included. 7. Entries must be accompanied by an article which explains how to use the program, what it does, and so on. If your program employs any new or unusual techniques that you think will be of interest to other ST programmers, you can also describe how the program works. 8. Submissions which do not win a prize and are not accepted for publication will be returned only if accompanied by a self-addressed, stamped

 mailer.9. All judging will be handled by the staff of COMPUTE! Publications, Inc. All decisions regarding contest entries and acceptances will be solely at the
discretion of COMPUTE! Publications, Inc., and all decisions are final. This includes decisions regarding creativity, similarity among entries, and so forth.
10. Winners will be announced by COMPUTE! Publications, Inc. in late 1986.
11. This contest is void where prohibited by law. Full-time, part-time \& previous employees of COMPUTE! Publications, Inc., and Capital Cities/ American Broadcasting Corporation are ineligible for the contest, but may still submit work for publication at standard rates.

## Every Contest Entry Must Contain This Form:

I warrant that the program presently entitled.
is my own original work and that the work has not been submitted for consideration elsewhere, nor has it been previously published. If my work is accepted by you, I understand that your decision as to the selection of winners and awarding of prizes is final and without recourse on my part. I agree, should you select my submission, to sign your standard contract, which includes assignment of the copyright of the program to COMPUTE!, and to allow you to use my name and image in promotional materials and other forms. (If you are under age eighteen, your parent or legal guardian must sign for you.)

## Announcing major news for Atari ST users:

## A bimonthly magazine devoted exclusively to Atari ST enthusiasts that includes a disk containing all of the programs found in each issue.

Atari has proven the pessimists wrong. The Atari 520ST and 1040ST have become the bestsellers among the new generation of personal computers. Both are breakthroughs in price and performance, and the community of ST owners is growing by thousands each month.

That's one reason why COMPUTE! Publications is announcing a new magazine specially designed for ST users. At the same time, we recognize that the power of the ST presents a unique challenge to magazines which publish program listings. That's why we're including a $3^{1 / 2}$-inch disk that contains every program found in each issue-ready to load and run. No more typing!
Here's what you'll get in every issue of COMPUTE!'s Atari ST Disk \& Magazine:

- Top-quality programs. Utilities. Games. Educational programs for youngsters. Application programs for home and business. And since all the programs will be on disk, there are few limitations on length or languages. A typical disk might contain an elaborate adventure game written in BASIC, a programming utility written in machine language, a dazzling graphics demo in compiled Pascal, and a useful home or business application written in Forth or C.
- Neochrome of the Month. Take a look at what computer artists are doing with the Atari ST. Each issue's disk contains a Neochrome picture file ready for you to load and admire. Are you an artist yourself? Send us a picture of your own, and we'll pay you if it's published.
- Regular columns. If you're a programmer-or would like to be-you'll love our columns on ST programming techniques and the $C$ language. Or check out our column on the latest events and happenings throughout the ST community. Or send your questions and helpful hints to our Reader's Feedback column.
- Reviews. Honest evaluations of the latest software and hardware for the Atari ST.
- News \& Products. A comprehensive listing of the newest releases for your ST.

- And more: Interviews with ST newsmakers, reports on the latest industry trade shows, and overviews of significant new product introductions.
Starting with the October issue (available September 1), COMPUTE!'s Atari ST Disk \& Magazine will be found on newsstands nationwide for only $\$ 12.95$ per copy, including disk. Or it can be delivered directly to your mailbox six times a year for only $\$ 59.95$-a savings of over 20 percent.

## As a special bonus, if you order a prepaid subscription before August 1, you'll get the first issue absolutely free!

To order, call 800-346-6767. In NY 212-887-8525 or send check or money order to

All rights reserved, ISSN 0194-357X.

Last month, we hinted at a significant pending announcement for Atari ST users. Here at COMPUTE!, one of the most exciting things we do is launch new publications. We are, without parallel, the most successful and balanced publishing house in the industry of consumer computing. A decision on our part to support a computer manufacturer and a computer system with a dedicated magazine is not made lightly. We are extremely pleased, therefore, to announce that ABC Publishing, our parent company, has committed full support to our launch of COMPUTE!'s Atari ST Disk \& Magazine.

This will be our very first product that comes as a magazine/disk combination only. Whether you subscribe or purchase it from a newsstand, you'll get a magazine containing the articles and a disk containing the programs. It's a single, united product. And one we're quite proud of.

No publisher in this industry has been as successful as COMPUTE! Publications at marrying diverse publishing technologies. When we introduced COMPUTE!'s GAZETTE DISK, other disk products were selling a few hundred copies at $\$ 30$ or more per issue. We launched the GAZETTE DISK at $\$ 12.95$ and created, with your massive support, an overnight price move in the industry. The GAZETTE DISK is today the bestselling product of its kind in the world, circulating tens of thousands of copies per month.

We fully expect COMPUTE!'s Atari ST Disk \& Magazine to accomplish the same feat. At launch, our newsstand distribution will rival that of a magazine-only publication. Logistically, there are numerous difficulties involved in binding tens of thousands of disks into magazines heading for newsstands. It's an exciting undertaking, and we'll be anxiously awaiting the results of the first newsstand sales. Watch for the premiere issue of COMPUTE!'s Atari ST Disk \& Magazine in September at your local newsstand that handles COMPUTE! and COMPUTE!'s GAZETTE. We have every hope that it will become a collector's item.

You'll find complete details of our announcement on page 3 of this issue. On page 2 you'll also find a rather interesting contest announcement. We're offering $\$ 10,000$ in prizes for the very best Atari ST programs and articles. Good luck!

## Commodore 64 Forever

At this June's Consumer Electronics Show
in Chicago, Commodore plans to unveil something that may seem ho-hum to many people. In an age of $16 / 32$-bit Amigas and STs with megabytes of memory, Commodore is preparing to announce a revamped version of the Commodore 64 -basically the same computer in shiny new wrappings. Dubbed the Commodore 64C, it will be a fully compatible 64 in a Commodore 128 -style case. Enclosed in the package will be a floppy disk containing a terminal program for accessing the QuantumLink information service, and GEOS, the graphics-oriented operating system and user interface. Expected price: between $\$ 160$ and $\$ 180$.

This may not seem too excitingunless you're a Commodore enthusiast or someone searching for an inexpensive home computer system. From our viewpoint, it's the most exciting 64-related announcement in the past three years. Loud and clear, it broadcasts three important messages:

1. Despite its commitment to establishing the Amiga as its flagship personal computer, Commodore is not abandoning the millions of 64 owners. The Commodore 64C shows that Commodore is determined to continue its support of what has become the world's most popular home computer.
2. The Commodore 64 market will remain a significant source of revenue for software developers, and may even keep expanding.
3. As the bundling of GEOS shows, the 64 is still evolving, growing more powerful and easy to use, and is an exceptional value for people who need a functional computer system for under $\$ 500$.

Like Apple's slogan when it introduced the Apple IIc-"Apple II For-ever"-Commodore is declaring, in effect, "Commodore 64 Forever."

Forever is a long time, and we don't really think the 64 will be around quite that long. Still, Commodore's renewed commitment to the 64 reassures those who have wondered if their computers would soon be "orphans." COMPUTE! has received many letters from readers who feared that the 64 market would dry up and vanish now that Commodore is preoccupied with the Amiga and 128. And actually, as we reported several issues ago, Commodore did attempt to shut down 64 production more than once last year. But each time, the unabated hunger for this four-year-old machine swamped

Commodore with orders, and the company was forced to restart production and rethink its strategy. The 64 refuses to die.

So Commodore is taking advantage of the situation by bringing the computer up-to-date without sacrificing its compatibility with the thousands of programs and peripherals already on the market. Here is what Commodore plans to announce at CES:

- The 64 C in a more professionallooking Commodore 128 -style case (minus the 128's numeric keypad);
- A bundled disk containing GEOS (Graphics Environment Operating System) and QuantumLink software. GEOS is patterned after the desktops found on the Macintosh, Atari ST, and Amigawindows, icons, pull-down menus, bitmapped graphics, and multiple onscreen type fonts. GEOS includes several integrated application programs and desk accessories, including GEOpaint, GEOwrite, a calculator, notepad, and clock. In addition, GEOS significantly speeds up disk access without modifying the 1541 drive. (For more details on GEOS, see our Winter CES report in the April 1986 issue of COMPUTE!.)
- On the flip side of the disk, 64C buyers will get the special terminal software necessary to access QuantumLink, the online communications service specially tailored to Commodore users.
- The 1541 drive will also get a sleek new case to match the 64 C .
- Memory expansion up to 128 K and 512 K RAM for the 64 and 128.
- A $31 / 2$-inch floppy disk drive for the 64 and 64 C , priced around $\$ 225$.

All in all, it's an interesting series of announcements, and an encouraging development for Commodore 64 enthusiasts everywhere.

Robert C. Lock,
Editor-In-Chief

Editor

## HF YOUPE READYFOR HOME BANKING BUT YOUR BANK ISNYT...

## YOUPRE READYFOR CHASE.

## NEW YORK'S PREMIER HOME BANKING AND INFORMATION SYSTEM.

You're ready for a way to make the most of your time, your money, and your personal compiuter, and here it is. SPECTRUM, ${ }^{\text {SM }}$ the home banking and information system from The Chase Manhattan Bank, N.A.

BANKING JUST GOT A LOT MORE PERSONAL.
Just switch on your PC, and you've got the undivided attention of a banker, a broker, and a bookkeeper. Right in your own home, your office, or wherever. 24 hours a day, 7 days a week. With complete security.

## IT'S WHAT HOME BANKING

 SHOULD BE. EASYTouch a button to check your balances; transfer funds between checking, savings, money market and other accounts; pay bills to anybody, anywhere; and keep records. Touch another and you've got key financial planning information to set goals... and meet them. Touch still another and a complete investment menu is at your service: check the market, get the bottom line on over 4600 companies with S\&P Online ${ }^{\text {TM }}$ from Standard \& Poor's Corporation, track your portfolio, even
trade stocks and options at a discount through
Rose \& Company, a Chase affiliate.
If you do have any questions, there's even a real person you can call-16 hours a day.
HOME BANKING, AND THEN SOME.
Since there's more to life than banking and finance, there's more to SPECTRUM than that.

Through our electronic bulletin board, you can find a squash partner, a recipe for pasta al pesto, maybe even a ski house share up in Vermont!

## THE BIG PAYOFF:

The good news is that all this starts at just $\$ 5$ a month, with the first 2 months of service free. There are no sign-up fees or connect time charges, and, thanks to our 800 number, even the phone calls are free.

So if the only thing that's kept you from home banking is your bank, give us a call. We'll make it easy for you to open an account with us to get on-line with SPECTRUM.

You can still use your other bank for other financial needs.

But if you're ready for New York's premier home banking and information system, chances are, you're ready for Chase.

 Computer Projectsfor Commodore and Atari Personal Computers

## COMPUTE!'s First Book of the Commodore 128

A spectacular collection of articles and programs exclusively for the Commodore 128 in 128 mode. Edited
The editors at COMPUTE! Publications have collected some of the best games, programs, and tutorials for the Commodore 128 from COMPUTE! and COMPUTE!'s Gazette, plus some never-beforepublished articles and programs. Learn how to create windows, program sound, and make disks autoload. You'll even find a map of all the important memory locations. There's something for every 128 user. All programs run in 128 mode. A disk is available which includes programs in the book, \$12.95.
\$14.95 ISBN 0-87455-059-9

## Electronic Computer Projects

Learn how to build all kinds of new devices to interface with your computer from inexpensive, available parts.
For the Commodore 64, 128, VIC, and any eight-bit Atari personal computer.
Soori Sivakumaran
This introduction to digital electronics and computer interfacing is the easy way to learn how computers interact with the outside world. Using a Commodore 64,128, VIC, or any eight-bit Atari computer and Electronic Computer Projects, you'll be guided through the steps to building a joystick, light pen, game paddle, and numerous other devices. And since each project is independent from the others, you can choose only those projects that interest you. All the projects can be built at home and most require fewer than half a dozen parts.
\$9.95 ISBN 0-87455-052-1

Visit your local book or computer store for these new titles. Or order directly from COMPUTE! Books. Call toll-free 800-346-6767 (in NY 212-887-8525) or write COMPUTE! Books, P.O. Box 5038, F.D.R. Station, New York, NY 10150.

## The Ideal BASIC Style

Some time ago I read a letter in your magazine regarding crunching of program listings and the effect this has on readability. You replied that this was to save memory and magazine space. I would like to suggest a reasonable compromise between readability and the elimination of spaces. In my view, any statement that juxtaposes two letters (for instance, $\mathrm{FORT}=1 \mathrm{TO} 10$ or $\mathrm{IFS}=5$ ) would benefit greatly from extra spaces (FOR T=1 TO 10 or IF $S=5$ ). But if a number follows a letter (as in GOTO600 or THEN470), the statement is understandable even without an extra space. I think DATA should always have a following space so the first value stands out clearly. You are often inconsistent in this, even within the same program listing. As to multiple statements in one line, this in itself creates no problems and is necessary in some cases. But I don't believe that completely unrelated statements should be put on the same line simply to fill up the line.

Line numbering is another area. You use the time-honored decade numbering (line increments of ten), which is fine when developing a program. Finished programs are usually renumbered for neatness, but I don't see why nine skipped numbers are necessary. I suggest that you use every other number instead ( $1,3,5$, and so on). This would allow someone to insert a STOP or GOTO while checking for typing errors or making minor alterations. The big advantage of this system is that decade numbers could have special meanings as important entry points or the beginning of a new group of closely related statements. For example, a complex FOR-NEXT loop might use several lines, then jump to the next decade line number for a new group of related
statements. It would be much easier to follow and understand the flow pattern.

I also feel there could be at least partial standardization of some of the most common variable names. For instance, the variables $\mathrm{I}, \mathrm{J}$, and K are ordinarily used as "junk" variables (counters within loops, and so on). The variables $X$ and $Y$ are frequently used to specify horizontal and vertical coordinates. But many others are commonly used as well: SA for starting address, EA for ending address, CK for checksum, and so forth. You could publish a list of suggested variable names and encourage programmers to stick to it.

Don R. King
As long as programmers use BASIC, there will be discussions about what sort of style and structure BASIC programs ought to have. The reason for the controversy is familiar. BASIC imposes few structural constraints on the programmer, so the language is easy to learn and works well for improvisational programming and quick experiments. But its lack of structure also makes it possible to write tangled, illogical "spaghetti" code. Since BASIC doesn't force you into a predetermined mold, a program can take nearly any form. More structured programming languages such as Pascal generate more readable code, but demand more forethought on the programmer's part.

Most of the programs we publish are submissions from readers.Generally, we modify these programs only to eliminate any bugs that appear during testing or to add functional improvements. Any time you change someone else's program, you increase the likelihood of inadvertently creating new bugs which even the author may not have anticipated. Given the number of programs we publish and the constraints of monthly deadlines, it's not practical for us to rewrite working programs merely to improve their readability.

A carefully planned numbering scheme can add to a program's readability. But our programs are meant to be typed in from a printed listing as well as studied. So we need to do everything possible to help readers type the programs without errors. Numbering in regular increments makes it easier to keep your place in the program than if the increments changed at unpredictable intervals. Uniform num-
bering also helps readers spot lines that have been left out altogether (a typing error that no proofreader program can catch). However, sometimes even the simple act of renumbering a program can introduce new bugs-as has happened to us in the past.

It's also true that if everyone followed the same stylistic conventions, BASIC programs would be more readable. The difficult part is getting programmers to go along with the conventions you choose, especially considering that each version of BASIC has its own peculiarities. For instance, Commodore BASIC doesn't require spaces after keywords (and omitting spaces speeds program execution), but some other versions of Microsoft BASIC insist on a separating space. Other BASICs, such as Atari BASIC, automatically insert spaces for readability if you leave them out.

Different dialects of BASIC also include different keywords. For instance, NAME is a legal variable name in Commodore BASIC, but it's treated as a reserved word in IBM BASICA and Amiga BASIC. In Commodore and Apple BASICs, only the first two characters of the variable name are significant, and you may not embed keywords in variable names. But IBM, Atari, and Amiga BASICs permit long, descriptive variable names such as MousePosition or MenuFlag which can include embedded keywords. The list of differences goes on and on. Given the diversity among BASIC dialects and the absence of standardization, any list of preferred variable names would have to be exceedingly general and geared toward the lowest common denominator.

As time goes by, Microsoft BASIC seems to be taking over as the de facto standard for the language. Newer, more powerful computers such as the Macintosh, Atari ST, and Amiga all offer versions of BASIC that more closely resemble IBM BASICA. With the exception of graphics and sound statements, which are necessarily hardware-specific, a program that runs on the IBM, Mac, or Amiga will probably run on any of the others with only slight modifications. If this trend continues, we may someday reach the point where BASIC style becomes more homogeneous.

# BEFORE YOU BUY INSURANCF, EXAMINETHEEVDENCE. 

An agent who works for one company can only offer you the

An Independent Insurance Agent represents several companies. So your Independent Agent can help you select the right coverage af the right price because there are more policies from which to choose.

The evidence is clear.

## Faster Fractals In Forth

I enjoyed reading Paul Carlson's article on fractal graphics for the IBM PC/PCjr (COMPUTE!, March 1986). His explanations were very clear. But it must have been a real trial for him to develop the BASIC version of the "Eight Thousand Dragons" program. We would like to show the beauty of fractals when written with a language that supports recursion. Here is an example of Forth code that does the same thing. It's written for Mach1, our Forth compiler for the Apple Macintosh and Atari ST. The execution time for a fourteenth-degree dragon is only three minutes.

## Reading The Atari Touch Tablet In BASIC

I am currently working on an Atari program that lets me create highresolution drawings in graphics mode 15. However, the drawing should be done with the Atari Touch Tablet. How can a program read the Touch Tablet coordinates?

## Peter Hinz

Reading coordinates from the Atari Touch Tablet is very easy in Atari BASIC. The Touch Tablet returns the same values as paddle controllers, and Atari BASIC contains a function called PADDLE for reading these controllers. Use PADDLE(0) to

: Drag RECURSIVE \{ x1 y1 x2 y2 x3 y3 k| x4 y4 x5 y5 \} PAUSE
k $0=$
IF
(if $k=0$ just draw and return)
(else continue breaking lines down)
k $1-\gg x 4$
$\mathrm{x} 1 \times 2+2 / \mathrm{y} 2 \mathrm{y} 1-2 /-\rightarrow>x 4$ $\mathrm{y} 1 \mathrm{y} 2+2 / \mathrm{x} 2 \mathrm{x} 1-2 /+->\mathrm{y} 4$ $\mathrm{x} 2 \mathrm{x} 3+2 / \mathrm{y} 3 \mathrm{y} 2-2 /+\rightarrow \mathrm{x} 5$ $\mathrm{y} 2 \mathrm{y} 3+2 / \mathrm{x} 3 \times 2-2 /-\rightarrow \mathrm{y} 5$ x1 y1 x4 y4 x2 y2 k Drag x2 y2 x5 y5 x3 y 3 k Drag
THEN ;
:Dragon \{iters -- \}
( '14 dragon' gives the best results)

CLS
100190 CALL MoveTo
10019022862356190 iters Drag
( place pen at beginning)
( start with initial seed)

## Terry Noyes

Although recursive routines (program segments that call themselves) are ordinarily taboo in BASIC, they're not only feasible, but encouraged in other languages such as Logo and Forth. Besides speeding execution, recursion produces compact, elegant code, as this example shows. Thanks for the demonstration.
read the horizontal position of the stylus on the tablet, and PADDLE(1) to read the vertical position (assuming that the tablet is plugged into controller port 1). Both functions return values ranging from 1 to 228. When nothing is touching the tablet surface, these functions return the value 228.

Reading the Touch Tablet buttons is just as easy. Use the PTRIG(0) function to
read the left button, and PTRIG(1) to read the right button (again, assuming that the tablet is plugged into port 1). When a button is pressed, these functions return a value of 0 . Otherwise, they return a value of 1 .

The button on the Touch Tablet's stylus works a little differently. To detect this button press, use the STICK(0) function (normally intended for reading a joystick). If the stylus button is pressed, STICK(0) returns a value of 14 . Otherwise, it returns the value 15.

The following example program prints the tablet coordinates on the screen along with messages when any of the buttons are pressed:

```
BN 1\varnothing X=PADDLE (\emptyset):Y=PADDLE (1
    )
MM 2\emptyset PRINT }X,
ID 3\emptyset IF PTRIG(\varnothing)=\emptyset THEN PRI
        NT "LEFT BUTTON PRESSE
        D"
NI 4\varnothing IF PTRIG(1)=\varnothing THEN PRI
        NT "RIGHT BUTTON PRESS
        ED"
HL 5\emptyset IF STICK(\varnothing)=14 THEN PR
        INT "STYLUS BUTTON PRE
        SSED"
AA G\emptyset GOTO 1\emptyset
```

## Safe Zones In IBM BASIC

Is there any way to store a few characters or flags in the IBM PC's memory that will survive the BASIC RUN command? I want my program to be able to "learn" as it runs and remember what it has learned each time it is run.
H. Beck

IBM BASIC's CLEAR command gives you the ability to create a safe area of RAM of almost any size. Besides deleting all variables, CLEAR controls the amount of memory available to BASIC. By adding a comma and a parameter to the CLEAR command, you can make the BASIC workspace smaller than usual, reserving the extra memory for yourself. The workspace is initially 65,536 bytes, but it's easy to reserve some memory at the top of that space. Use this format:

## CLEAR ,workspace

where workspace is a number less than 65536. To calculate the correct value, subtract from 65536 the number of bytes you want to protect. For instance, the command CLEAR , 65280 reserves the last 256 bytes $(65536-256=65280)$ of BASIC workspace for your use.

When you type RUN after a CLEAR statement like this, the size of the workspace is reset to its default but the data in the reserved area is not affected. As long as the next program begins with a similar CLEAR statement, it can PEEK into the reserved area and find the values that the previous program POKEd there. Here's a
simple program that stores some values in a 256-byte reserved area:
10 CLEAR,65280
20 FOR A $=0$ TO 255
30 POKE A+65280,A
40 NEXT
After you run the program, enter and run this program to read the stored values back.
10 CLEAR, 65280
20 FOR A $=0$ TO 255
30 PRINT PEEK (A+65280)
40 NEXT

## Scanning The 128's ALT Key

Please tell me how to read the ALT key on the Commodore 128.
J. C. Vollmer

The 128's ALT key cannot be polled like the other keys. Instead, your program must PEEK location 211, where the system stores information about five special keys: SHIFT, CONTROL, ALT, CAPS LOCK, and the Commodore key. When you press one of these keys, it sets a certain bit in this location:

| Key | Bit | PEEK(211) Value |
| :--- | :---: | :---: |
| SHIFT | 0 | 1 |
| Commodore | 1 | 2 |
| CONTROL | 2 | 4 |
| ALT | 3 | 8 |
| CAPS LOCK | 4 | 16 |

Thus, if PEEK(211) equals 8, you know the ALT key is pressed. Since each key has its own signal bit, the values from location 211 are additive. If PEEK(211) equals 9, for instance, both SHIFT and ALT are pressed. When SHIFT and CONTROL are pressed, location 211 holds 5, and so forth.

## Correction For Casio Review

I enjoyed reading your January 1986 review of The Music Shop for MIDI and the Casio CZ-101 synthesizer. In fact, I became inspired and bought the same system, after having exhausted the 64's musical capabilities. You mentioned a problem with accessing all the features of the CZ-101 synthesizer. Perhaps I obtained an updated version of The Music Shop for MIDI because I have not had the same experience. All 48 timbres can be accessed (the basic presets plus those in internal memory or cartridge memory). In addition, four-voice polyphonic music is possible within the program using the programmable MIDI features (channeling the four solo voices). Casio's COSMO series of synthesizers, which includes the CZ-101, is capable of playing up to eight timbres (four on the CZ-101) on a single slave unit. Have you looked into other types of MIDI software presently available?

## DESIGNING YOUR OWN COMPUTER GAMES JUST BECAME EASY.

Have a great idea for a game? Don't have enough time to learn how to turn it into software? Your magic wand has just arrived. Activision proudly presents Garry Kitchen's GameMaker: The Computer Game Design Kit.". We've packed five professional-quality design tools into one easy-to-use program.

SceneMaker: Design the set. Select from preprogrammed backgrounds like space, jungle or river scenes or create a world of your own.

MusicMaker: Compose the score. Set the mood with just the right music or create triumphant interludes.

SoundMaker: What do you get when you cross a "clunk!" with a "boom?" From explosions to train whistles-smash, blast and whoosh your way into a smorgasbord of sound effects.
who and what's what.

The Editor: The grand finale. Look at all the components, choose some and edit others, polish it and . . . bring it to life. We've even given you a blank disk so you can send it to a friend... or publisher.

GameMaker: Unleash the power of your computer-and your imagination. Then, revel in the creation of a true original ... a game of your own.

## ACTIVISION

 Commodore 64 or 128 and compatible computers.And your Earls and Viscounts. If you've got royal ancestors, we have the noble software that can help you trace them down.
Family Roots and your Apple, IBM, Commodore, Kaypro*, and many others, offer individual and group sheets, charts, name indices, general search and text capabilities. Adapts

Put up your dukes! to most disk drives, printers, and screens. You get more utility programs, plus lots of personal control. A comprehensive (new) manual is included.
All for just $\$ 185$.
Write or call today for more information and a free brochure.

## Eric Habeck

Thanks to you and to Don Williams (the programmer who created The Music Shop and The Music Shop for MIDI) for alerting us to the misstatement. The 64 is very popular with musicians and sound enthusiasts because of its low cost and built-in sound capabilities. As the MIDI standard becomes more widely accepted, we're likely to see even more in the way of music software for the 64 . We'll continue to review new products as time and space permit.

## Customizing SpeedScript 3.0

The "SpeedScript Customizer" program that appeared in the September 1984 issue of COMPUTE!'s GAZETTE allows you to change the default settings and formatting commands in SpeedScript 1.0 to fit your own preferences. But that program doesn't work with SpeedScript 3.0 or 3.2. Do you have an update of the program or the necessary POKEs to allow the same customization for the most recent versions of SpeedScript?

## Bruce Patten

It just so happens that another reader wrote in with the very information you're seeking:
"SpeedScript Customizer" doesn't work with SpeedScript 3.0 or 3.2. But I have discovered the POKEs for customizing all of the same parameters for the newest versions of SpeedScript. Here are the default (normal) values and the locations that control them:

## Default

| Location | Value | Parameter |
| :--- | ---: | :--- |
| 5722 | 5 | Left margin |
| 5723 | 75 | Right margin |
| 5724 | 66 | Page length |
| 5725 | 5 | Top margin |
| 5726 | 58 | Bottom margin |
| 5727 | 1 | Spacing |
| 5728 | 1 | Wait (1= go ahead) |
| 5729 | 1 | @ start numbering |
|  |  | pages at (LSB) |
| 5730 | 0 | (MSB) |
| 5731 | 1 | ? starting printing at |
|  |  | page (LSB) |
| 5732 | 0 | (MSB) |
| 5733 | 80 | x columns across |
| 5734 | 27 | 1 printkey 1 |
| 5735 | 14 | 2 printkey 2 |
| 5736 | 15 | 3 printkey 3 |
| 5737 | 18 | 4 printkey 4 |

To customize your program, load SpeedScript 3.0 or 3.2 into memory, then POKE the desired values into the appropriate memory locations. For example, POKE 5722,3 makes the left margin setting default to 3 instead of 5 . Then save the program using a different name. For instance, I have a frequent
need to print postcards, so I set the left margin at 3 , right margin at 35 , columns at 40, top margin at 3 , bottom margin at 18 , and page length at 2 . If you want to start numbering pages or start printing pages at a page lower than 256, POKE the desired value in the first of the two locations indicated. For instance, to start numbering pages at page 3, you would POKE 5729,3. To start at a page higher than 255, you must POKE two values in low byte/high byte format. The low byte of the value goes into the lower location.

Allen Perkins
Thank you for the information. As mentioned in the original SpeedScript article, most of these settings have to do with formatting hardcopy printouts.

## Apple RESET Vectoring

Is there any way to make the Apple II jump to a specific machine language subroutine after the RESET key has been hit?

Jose A. Colon Olivo
This can done by changing the two-byte RESET vector at location 1010 (\$03F2). The most direct way to alter the vector is to POKE the starting address of your machine language program into locations 1010-1011 in low byte/high byte format, then update these pointers with CALL -1169. When you hit RESET, the Apple checks the vector, goes to the indicated location, and runs your program. As an example, suppose you wish to execute the following routine which prints an A on the screen upon RESET:

## 0300 LDA \#\$C1 <br> 0302 JSR \$FDF0 <br> 0305 JMP \$03D0

The first step is to determine the high and low bytes of the starting address in decimal. The hexadecimal number $\$ 0300$ is expressed as decimal 768. So, the high and low bytes of the starting address are:
$\mathrm{HI}=\mathrm{INT}(768 / 256)=3$
$\mathrm{LO}=768-\mathrm{HI}^{*} 256=0$
Next, POKE the address values in 1010 and 1011, and execute the CALL to update the pointers:

## POKE 1010,LO

POKE 1011,HI
CALL - 1169
When you hit RESET, the routine executes. Notice that the ML routine ends with JMP \$03D0. Because the routine is jumped to directly, it leaves no return address on the microprocessor's stack. If it had ended with an RTS, you'd wind up back in the machine language monitor after it's done. To avoid this unwanted result, you must exit with a JMP to the BASIC soft reentry point at \$03D0.

SUPPORT FROM COMPUTE! BOOKS
Everything for the Amiga. From BASIC beginner's guides to advanced programming handbooks, COMPUTE! offers you information-packed tutorials, reference guides, programming examples, ready-to-enter applications, and games to help you develop your computing skills on Commodore's Amiga.

## COMPUTEI's AmlgaDOS

Reference Gulde
Arlan R. Levitan and Sheldon Leemon A comprehensive tutorial and reference guide to the powerful AmigaDOS-the operating system underlying the Workbench and Intuition-this book offers information useful to every Amiga owner. It defines and illustrates all DOS commands, and shows you how to create file directories, access peripherals, run batch file programs, and avoid "disk shuffle." The screen- and line-oriented text editors are explained in detail. Numerous examples and techniques explain how to use AmigaDOS to make operating your Amiga both convenient and efficient.
\$14.95 ISBN 0-87455-047-5

## Elementary Amiga BASIC

C. Regena

Here's your introduction to the new and powerful BASIC on the Amiga personal computer. The Amiga's impressive graphics, animation, and sound can be unlocked with the right commands, and BASIC is the place to start. Complete descriptions of Amiga BASIC's commands, syntax, and organization take you from the beginner level to a full-fledged programmer. Plus, the book offers you ready-to-type-in programs and subroutines while showing you how to write your own programs. There is a disk available which includes the programs in the book, $\$ 12.95$. This title is also available as a book/disk combination for $\$ 29.95$ (057-2).
\$14.95 ISBN 0-87455-041-6

## COMPUTEI's Amiga

Programmer's Guide
Edited
Your tutorial and reference manual to AmigaDOS, BASIC, Intuition, and other important software tools which accompany the new Amiga, COMPUTEI's Amiga Programmer's Guide is a clear and thorough guide to the inner workings of this fascinating newgeneration computer. The great speed of its 68000 microprocessor, coupled with the versatility of the Amiga-specific graphics and sound, makes the Amiga one of the most powerful computers available today. This book is the key to accessing the Amiga's speed and power.
\$16.95 ISBN 0-87455-028-9

## Advanced Amiga BASIC

Tom R. Halfhill and Charles Brannon This guide to applications programming on Commodore's new Amiga contains everything an intermediate programmer requires to begin creating sophisticated software on this powerful machine, including several ready-to-type-in programs. Clear, yet comprehensive documentation and examples cover advanced BASIC commands, designing graphic applications, generating sound and music, using the Amiga's built-in speech synthesizer, creating a user interface, and programming the computer's peripherals. There is a disk available which includes the programs in the book, $\$ 15.95$. (June release)
\$16.95 ISBN 0-87455-045-9

> Look for these books at your local book or computer store. Or order directly from COMPUTE!.
> Call toll-free 1-800-346-6767 (in NY 212-887-8525).

COMPUTE!'s Beginners Guide to
the Amiga the Amiga
Dan McNeill
Written in a lively and entertaining style, this book teaches you everything a beginner needs to know to get started quickly with the Amiga from Commodore. You will learn about setting up the system, all the most popular types of software, and details about the hardware. \$16.95 ISBN 0-87455-025-4

## Inside Amiga Graphics

Sheldon Leemon
The Amiga, Commodore's powerful new computer, is an extraordinarily impressive graphics machine. Easy to use, the Amiga can produce color graphics and excellent animation. You'll find thorough descriptions of the computer's abilities and the hardware required to create a complete graphics system. Software, too, is central to the Amiga's power, and complete tutorials show you how to get the most from the machine. (June release) \$16.95 ISBN 0-87455-040-8

COMPUTEI's KIds and the Amiga
Edward H. Carlson
The latest in this bestselling series written by Edward Carlson, COMPUTE!'s Kids and the Amiga, will acquaint you with BASIC. Over 30 sections-all with instructor notes, lessons, assignments, and lively illustrations-entertain and amuse you as you learn to program your new computer. Clear writing and concise examples make it easy for anyone-children and adults alike-to painlessly learn BASIC. (May release)
\$14.95 ISBN 0-87455-048-3
Please allow 4-6 weeks for delivery after your order is recelved.

The same technique can be used to make the computer run a BASIC program when RESET is hit. Simply POKE the location of the Applesoft RUN routine into the RESET vector and call the ML from the first line of a BASIC program (for instance, with CALL -768). This could be done with the following program line:
10 POKE 1010,102: POKE 1011,213: CALL

- 1169
In this case, you'd want to return to BASIC by ending the ML routine with RTS rather than JMP \$03D0.

## Machine Language Division

I own a Commodore 64 and am teaching myself machine language. There is only one problem preventing me from completing my first useful program-I can't write a program to divide by ten. The objective is to take a number in the range $0-255$ from memory and break it into each of its decimal parts. For example, 255 would break down into the digits 2,5 , and 5 .

## Kevin Owens

The 6502/6510 instruction set does not include a division instruction of any sort. Although it's possible to construct an ML routine for division, it is much easier and faster to use a method called successive subtraction. Here is the basic idea: Each power of ten from highest to lowest (in this case from 100 to 10 to 1) is subtracted from the number until you determine that the number has become negative. Each digit of the number is derived by counting the number of subtractions.

Below is the source code for a short program that displays any three-digit number at the upper-left corner of the screen. You'll need a machine language assembler to create the object code. (This program is written in PAL assembler format for the Commodore 64. Slight modifications are needed to assemble the code with a different assembler or to make the program work on a different 6502 computer.) Once the program is assembled, enter SYS 828: The program displays all the numbers from 0 to 255 in succession. The delay loop in line 130 gives you time to read each number. To see how fast numbers can be converted and displayed, remove this line and reassemble the program.

```
10 SYS 7øø:.OPT OO:*=828
\(2 \emptyset\) TEMP \(=2\)
30 LDA \#Ø:STA 53281:LDA \#147:J
    SR \$FFD2

$14 \emptyset$ LDY \#8:LDX \#ø:WT DEX:BNE W T: DEY:BNE WT
$15 \emptyset$ JMP START
$16 \emptyset$ DIGITS .BYT $1 \varnothing \varnothing, 1 \varnothing, 1$

## Atari BASIC Bugs

I have a very serious problem with my 16 K Atari 600 XL . Sometimes right after I've entered a line, the computer locks up and the only key that will work is SYSTEM RESET. But after I press RESET and enter another line, the computer locks up again.

## Tak Lee

You're experiencing the latest incarnation of the infamous Atari BASIC lockup bug. This bug afflicts two versions of Atari BASIC: the original version, known as revision $A$, which was supplied as a cartridge for the 400, 800, and 1200XL; and revision $B$, which is built into the 600XL and 800XL computers. The lockup bug takes a slightly different form in these two versions of BASIC. In revision A, BASIC is unable to delete (move downward in memory) a block of memory whose size is an exact multiple of 256 bytes. Most users encounter the bug in the form of a keyboard lockup after deleting program lines, but it can affect the movement of strings as well. To illustrate, type in the following program:

AO 1 D DIM A\$(256), B\$(256)
FD $2 \emptyset$ FOR $A=1$ TO 256: $A \$(A, A)$ ="B": NEXT A
6L $3 \varnothing B \$=A \$$
ID 4 © PRINT A\$:PRINT B\$
This creates a string variable, $A \$$, that consists of 256 B characters. Then it makes $B \$$ equal to $A \$$. When the program runs, you would expect it to print the letter B 512 times. Type RUN to see what happens instead. If you have revision $A$ BASIC, the first 256 characters are correct, but the remaining characters are garbage. This occurs because BASIC's memory move routine was unable to move the value of $A \$$ into $B \$$ correctly. To confirm that the bug applies only to blocks of memory in multiples of 256, try changing the number 256 in lines 10 and 20 to some other value.

This bug was corrected when revision B BASIC was prepared for the 600XL and 800XL. However, Atari's programmers got carried away and applied the same correction to a routine which didn't need fixing-the routine which inserts (moves upward) blocks of memory, which happens when you add a BASIC program line. As a result, revision B BASIC has its own lockup bug which rears its ugly head when program lines are inserted instead of deleted. Ironically, the revision B bug
may occur even more often than the old one-you add program lines more often than you delete them. As an example, turn your 600XL or 800XL off and back on, then enter the following line in direct mode:
DIM AS(249):AS ="TRASH"
Enter PRINT A\$ to see the variable value. Now enter this program line:

## 10 PRINT "THIS IS A TEST"

Before doing anything else, try to print the string again:

## PRINT AS

If you have revision $B$, your computer should be locked up, and pressing RESET won't recover. For more details, see Bill Wilkinson's "Insight: Atari" columns in the May and June 1985 issues of COMPUTE!.

The line-editing bug is not the only problem in early versions of Atari BASIC. Here's a list of some of the other bugs in revision A:

1. Because the value -0 is interpreted incorrectly, printing -0 yields garbage.
2. There's a problem with the precedence of the NOT operator which causes it to give unpredictable results in some cases. Type the following statement in direct mode when you have no other program in memory: PRINT NOT NOT 1.
3. LOCATE and GET statements may corrupt the internal buffer pointer. This can cause difficulties when trying to READ from DATA statements or when using the VAL function. If you have trouble with READ or VAL, use the statement $X \$=S T R \$(0)$ to reset the buffer pointer after a GET or LOCATE.

Revision B BASIC corrects some of the bugs from revision $A$, but also adds a few of its own. Here are some revision B bugs.

1. BASIC adds 16 bytes to the end of a program every time you LOAD or CLOAD $i$ it. After loading and saving the same program several times, you'll find that it has grown substantially. To remove the extra bytes, LIST the program to disk or tape and ENTER it back into memory. To avoid the problem, always use LIST/ ENTER instead of SAVE/LOAD.
2. CLOAD and CSAVE commands fail to turn off the sound after they're done. Use END or the statement SOUIND $0,0,0,0$ to silence it.
3. Occasionally, an ERROR 9 (array or string DIM error) wrongly occurs in a program line that contains a DIM statement. You may be able to fix this condition by LISTing the program to disk and ENTERing it again.

One solution is to get the newest Atari BASIC cartridge, revision $C$, from Atari Corp., Customer Product Service, P.O. Box 61657, Sunnyvale, CA 94088. It costs \$15. This is the same BASIC built into the Atari 65XE and 130XE models.

# GETUPTO2OO FUN-FILED PROCRAMS EACHYEARwhen you stbscribe now to courPute 

Subscribe to COMPUTE! today through this special introductory money-saving offer, and you'll be getting a lot more than just another computer magazine. That's because each issue of COMPUTE! comes complete with up to 20 all-new, action-packed programs.

Subscribe now and you can depend on a steady supply of high quality, fun-filled programs like Hickory Dickory Dock, Switchbox, TurboDisk, Home Financial Calculator, Turbo Tape, SpeedScript, SpeedCalc, and hundreds of other educational, home finance, and game programs the entire family can use all year long.

The superb programs you'll find in each issue are worth much, much more than the low subscription price.

And there's more to COMPUTE! than just exciting new programs. Month after month, COMPUTE!'s superb articles deliver the latest inside word on everything from languages to interfaces...from programming to disk drives.

Whether you're a novice or an experienced user, COMPUTE! is the magazine for you. So subscribe today. Return the enclosed card or call 1-800-247-5470 (in lowa, 1-800-532-1272).

## Down to BASICs

In one form or another, the BASIC programming language has been around since before the dawn of personal computing. Easy to learn, simple to use, and useful for a wide variety of tasks, BASIC has opened the
doors of computer programming for millions of people. Now, as a new generation of personal computers emerges, BASIC is continuing to evolve as a friendly and functional computer language-with a new look and feel.

Why BASIC? Why has this 22-year-old programming language-Beginner's All-purpose Symbolic Instruction Code-grown so immensely popular as an introduction to computer programming and as a general language? Despite its inherent limitations and numerous critics, BASIC remains the most widely taught and used language among computerists today.

The answers to these questions go back to a period before the advent of personal computing, in fact, years before a microcomputer was ever built. In the 1960s, the large mainframe computers ran programs by processing batches of punch cards-a system known as batch processing. These mainframes were machines that required a corps of trained operators to serve relatively untutored users. That average people would someday own and program powerful computers which fit on a desktop was unimaginable.

In those days, you didn't interact with a computer so much as present punch card offerings to it, and then wait for the computer to tell the computer operator to tell
you the answer. More often than not, the first result was that a mistake somewhere in your batch of cards made an answer impossible until you corrected the error and then resubmitted the batch for another run. Not only was the process tedious, but it also meant waiting in line for access to the computer. A computer could serve only one user at a time.

Today, we tend to take for granted our ability to communicate quickly and easily with computers. The proliferation of personal computers has meant that individuals can have control over when and how often they work with a computer. And that kind of accessibility means that many people need a relatively easy way to communicate with computers without having to rely on other people as translators.

The original BASIC grew out of a project started back in 1964 by Dartmouth College mathematics professors Dr. John G. Kemeny and Dr. Thomas E. Kurtz. Kemeny and Kurtz were working with students on a timesharing project that would allow several people to gain simultaneous access to the university's mainframe computers. As a part of

## Help your children learn the basics of computer programming with these two new entertaining and educational books from COMPUTEI.

\$14.95

0-87455-032-7
\$14.95

Each book contains easy-to-follow instructions, programming examples, quick reviews, and colorful illustrations. Written in COMPUTE!'s clear, easy-to-understand style, the books offer hours of entertainment while helping kids (and adults) learn to program in BASIC.

If you're acquainted with BASIC, you can easily write your own games and applications on Atari's ST or Commodore's 128 computers. Over 30 sections-all with instructor notes, lessons, assignments, and lively illustrations-entertain and amuse as you learn to use these powerful computers. COMPUTEI's Kids and the Atari ST and COMPUTEI's Kids and the Commodore 128, in the bestselling series from author Edward Carlson, are gentle introductions to programming your new computer. Clear writing and concise examples, both trademarks of this series, make it easy for anyone-child or adult-to learn BASIC painlessly.

Look for these and other books from COMPUIE!

the project, Kemeny and Kurtz developed BASIC, from which all subsequent versions have evolved. The professors wanted BASIC to be an easy-to-use general-purpose programming language for their mainframe system that would allow more people to communicate with the computer on their own.

By the 1970s, when the first microcomputers were becoming available, BASIC had come to be regarded as an excellent language

Developers of the original BASIC programming language, Dr. Thomas $E$. Kurtz (left) and Dr. John G. Kemeny, who now market a new version called True BASIC. <br> \title{

interpret every line of code while the program is running.

An alternative approach is a compiler. Popular compiled languages include Pascal, FORTRAN, C, COBOL, and some BASICs. Running a program with a compiler requires two steps. First, the compiler interprets all the commands in the program without carrying them out and creates a new version of the program on disk called object code, $p$-code, or run-time code. This file, incomprehensible to human eyes, is quite similar to a program written

In Amiga BASIC line numbers are unnecessary, and are replaced with labels that indicate subroutines and program divisions.
in machine language-it's a complex pattern of bits which is the only language that any computer really understands. After the compilation is completed, the object code can be run. Since all the commands in the program have already been interpreted by the compiler, the object code runs much faster than a program which must be interpreted one command at a time.

Unfortunately, the two-step process of compiling can take many minutes, which is frustrating for programmers-especially beginners. If the program contains an error, the whole process has to be repeated. It's not as frustrating as the old batch processing, but it's a step back in that direction.

Compiled languages also require more computer power than interpreted languages. They need faster processors and more memo-ry-sometimes 512 K of Random Access Memory (RAM) is scarcely enough for a compiler. This has largely prevented compilers from
becoming popular on personal computers, since until recently most machines were limited to 64 K of RAM. Because BASIC interpreters can be squeezed into as little as 8 K of RAM, BASIC was the logical choice for the first generation of microcomputers.

Most personal computer owners who are interested in programming quickly grow accustomed to the version of BASIC that comes with their machines. Some BASICs are built into the computer's Read Only Memory (ROM), while others are supplied on plug-in ROM cartridges or floppy disks. But there have been significant variations of BASIC even for the same brands of computers. Besides that, additional versions of BASIC are often made available by independent sources, as are packages which add enhancements to existing BASICs.

For example, Applesoft BASIC is a version of Microsoft BASIC that's used by Apple II-series computers. Integer BASIC, an earlier BASIC from Apple, was available in ROM on the original Apple II. Although faster than Applesoft BASIC, Integer BASIC doesn't allow floating-point math operations (the use of fractions) as does Applesoft. The Apple II+ machine came with Applesoft BASIC in ROM, while the Apple IIe and IIc computers have Applesoft BASIC on built-in language cards. (The $\mathrm{II}+$ can add a language card, too.)

Atari computers have had several different versions of BASIC available, as well as optional thirdparty BASIC languages. The Atari 400,800 , and 1200 XL computers come with an 8 K BASIC ROM cartridge, while the $600 \mathrm{XL}, 800 \mathrm{XL}$, and 130 XE computers have later revisions of BASIC built into ROM. There are also alternatives to Atari BASIC, such as Microsoft BASIC from Atari and BASIC XL and BASIC A+ from Optimized Systems Software (OSS) in San Jose, California.

Commodore 64 owners are familiar with the BASIC 2.0 version in their computers, the same version that appeared in the earlier VIC-20. Prior to 2.0, the earlier Commodore PET computer included a version 4.0. A variation

between BASIC 2.0 and BASIC 4.0, called BASIC 3.5 , was included in the Plus/4 and 16 computers. And the 128 includes a powerful version of BASIC, 7.0, that contains virtually all of the commands of the earlier BASICs.

But despite the differences among these forms of BASIC, they're all fairly similar in their organization. They're interpreted, giving immediate feedback to the user; they all use similar commands, variables, and functions; each line of BASIC begins with a line number;

ST BASIC has line numbers, but the GEM operating environment includes multiple windows, drop-down menus, and icons much like AmigaBASIC and Macintosh BASIC.

BASIC doesn't usually permit your computer to crash, so it's friendly to programmers; and access to printers and other peripherals is relatively easy to accomplish.

Within the past year, as the new Commodore Amiga and Atari ST computers have joined the Apple Macintosh-machines based on the more powerful 68000 micro-processor-computer users have been confronted with new BASIC languages that have several important differences from earlier versions. The Macintosh and the Amiga have BASIC languages that are almost identical, both created by Microsoft. The Amiga was inıtially released with a BASIC language called ABASIC, but that was superseded by the Microsoft version, called Amiga BASIC. The Atari ST, at this writing, has an ST BASIC from Atari, as well as several other versions of BASIC that should be available from third-party companies by the time you read this.

Both Amiga BASIC and Macin-
tosh BASIC abandon the line numbers used in previous BASICs. Instead, meaningful labels are used that identify sections of code and subroutines. Although ST BASIC does have line numbers, you can put labels within lines and direct subroutines to those labels.

The programming environment changes as well. Windowswith separate areas for your commands, the program listing, and the program output-take the place of the single screen you may be used to. With this system, you can actually see the program run while the program's code stays visible. Using a mouse, you can click on menu items like RUN and LIST instead of typing them in.

Macintosh BASIC, for example, offers several windows: a Command window to take your directions; two List windows, allowing you to have two different parts of the program onscreen at the same time; and an Output window which allows you to see the results of your programming. There are also programming tools that simplify your efforts. TRACE MODE, a debugging tool that can be switched on or off, highlights whatever line in your program is currently executing. The new BASICs also generally support the currently popular mouse environment, allowing you to create your own cus-tom-designed windows, pull-down menus, and dialog boxes.

ST BASIC is fundamentally similar to the BASICs you may have used on your eight-bit computer, but offers accessibility to windows, drop-down menus, and graphic icons from the GEM Desktop environment much like Amiga BASIC and Macintosh BASIC. There are actually four windows on the ST BASIC screen: Output, List, Command, and, hidden behind the first three, an Edit window.

It would, of course, be precipitate to conclude that the new BASICs represent the ultimate in manmachine communication. Rather, they seek to offer a higher level of power, ease, and efficiency to the computer programmer. Computer languages are continually evolving as the search continues for ever more effective methods by which man can interact with his increasingly intelligent inventions.

## 128 acs SENSAFIONAL

The complete compiler and development package. Speed up your programs $5 x$ to $35 x$. Many options: flexible memory management; choice of compiling to machine code, compact p-code or both. '128 version: 40 or 80 column monitor output and FAST-mode operation. ' 128 Compiler's extensive 80 -page programmer's guide covers compiler directives and options, two levels of optimization, memory usage, I/O handling, 80 column hi-res graphics, faster, higher precision math functions, speed and space saving tips, more. A great package that no software library should be without. 128 Compiler $\$ 59.95$

64 Compiler $\$ 39.95$

For school or software development. Learn C on your Commodore with our indepth tutorial. Compile C programs into fast machine language. C-128 version has added features: Unix ${ }^{T M}$-like operating system; 60K RAM disk for fast editing and compiling Linker combines up to 10 modules; Combine $\mathrm{M} / \mathrm{L}$ and C using CALL; 51 K available for object code; Fast loading ( $8 \mathrm{sec} .1571,18 \mathrm{sec} .1541$ ); Two standard I/O librarys plus two additional libraries-math functions (sin, cos, sqrt, etc.) \& $20+$ graphic commands (line, fill, dot, etc.).
$\begin{array}{ll}\mathrm{C}-128 & \$ 79.95 \\ \mathrm{C}-64 & \$ 59.95\end{array}$

Easily create professional high quality charts and graphs without programming. You can immediately change the scaling, labeling, axis, bar filling, etc. to suit your needs. Accepts data from CalcResult and MultiPlan. $\mathrm{C}-128$ version has $3 X$ the resolution of the ' 64 version. Outputs to most printers.
$\begin{array}{ll}\text { C-128 } & \$ 39.95 \\ \text { C-64 } & \$ 39.95\end{array}$

## PowerPlan

One of the most powerful spreadsheets with integrated graphics. Includes menu or keyword selections, online help screens, field protection, windowing, trig functions and more. PowerGraph, the graphics package, is included to create integrated graphs and charts.

C-64 \$39.95
Technical Analysis System for the C-64
\$59.95
Ada Compiler for the C-64
VideoBasic Language for the C-64

Remarkably easy-to-use interactive drawing package for accurate graphic designs. New dimensioning features to create exact scaled output to all major dot-matrix printers. Enhanced version allows you to input via keyboard or high quality lightpen. Two graphic screens for COPYing from one to the other. DRAW, LINE, BOX, CIRCLE, ARC, ELLIPSE available. FILL objects with preselected PATTERNS; add TEXT; SAVE and RECALL designs to/from disk. Define your own library of symbols/objects with the easy-to-use OBJECT MANAGEMENT SYSTEM-store up to 104 separate objects.

C-128 \$59.95
C-64 \$39.95

Not just a compiler, but a complete system for developing applications in Pascal with graphics and sound features. Extensive editor with search, replace, auto, renumber, etc. Standard J \& W compiler that generates fast machine code. If you want to learn Pascal or to develop software using the best tools available-SUPER Pascal is your first choice. C-128 \$59.95 C-64 \$59.95

## OTHER TITLES AVAILABLE:

## COBOL Compiler

Now you can learn COBOL, the most widely used commercial programing language, and learn COBOL on your 64. COBOL is easy to learn because its easy to read. COBOL Compiler package comes complete with Editor, Compiler, Interpreter and Symbolic Debugger.

C-64 \$39.95

## Personal Portfolio Manager

Complete portfolio management system for the individual or professional investor. Easily manage your portfolios, obtain up-to-the-minute quotes and news, and perform selected analysis. Enter quotes manually or automatically through Warner Computer Systems.

C-64 \$39.95

## Xper

XPER is the first "expert system" for the C-128 and C-64. While ordinary data base systems are good for reproducing facts, XPER can derive knowledge from a mountain of facts and help you make expert decisions. Large capacity. Complete with editing and reporting.

# and the 68000 

Kathy Yakal, Assistant Features Editor

A programming language written almost 15 years ago for a specific purpose-to develop an operating system for a mainframe computer-has been getting a lot of attention in the microcomputer community lately. C, a language described by many as simple, elegant, and powerful, is especially well-suited for programming the 68000 chip housed in the Commodore Amiga, Atari ST, and Apple Macintosh.

Cis a beguiling language. In structure and difficulty, it falls somewhere between machine language and a higher level language such as BASIC or Pascal. C was developed in 1972 by Dennis Ritchie, who wrote it specifically to design the UNIX operating system running on the PDP-11 (a mainframe computer). Though some mainframe and minicomputer programmers have chosen to use it in the years since, it's enjoying a renewed popularity with the advent of the new 68000 -based machines: the Atari ST, the Apple Macintosh, and the Commodore Amiga.

C is the language of choice for the Amiga and the ST, say many
programmers, for four main reasons. First, its basic command structure is quite concise, but can be extended by individual programmers for specific functions. Second, its relative closeness to actual machine language gives the programmer tremendous power. Third, there is a harmony between the 68000 microprocessor and the C language; 68000 machine language itself supports $C$ constructs, thanks in part to the similarities between the PDP-11 and the 68000. Finally, and perhaps most important for the home computer market, programs written in C on one 68000 -based machine can be more easily and quickly transported to another computer than can programs written in many other languages.

Programmers consider several factors when deciding what language to use. Of course, everyone has favorites based on personal experience, but the physical capabilities of individual computers and the type of application being written necessarily create some restrictions.

Just as some computers are designed to support specific lan-
guages, some languages have been developed to support specific applications. You could accomplish almost anything in almost any language, but there is significant variability between languages in the efficiency of program writing and excecuting. Some languages are simply more appropriate than others for specific jobs.

One of the first high-level languages, FORTRAN, was written in 1954, and is geared especially for scientific formula translation. $\mathrm{CO}-$ BOL, developed around the same time, best supports business applications. BASIC and Pascal were intended to be teaching languages, sometimes making them unwieldy for particular applications.

C, written to develop an entire operating system, is less applica-tion- and machine-specific, and is amenable to various kinds of programs. Its skeletal architecture allows programmers-once they've learned the sparse command struc-ture-to add their own routines, commands, and input/output functions called libraries (standard C libraries are also available commercially). It's really like the construction of an onion: You have a tiny seed in the center and layer upon layer covering it up. And the fact that input/output is extrinsic to the C language makes for greater portability.

So even though the language itself is small, you can end up with very large programs if you don't economize on your use of libraries, warns Tom Hospelhorn, senior analyst at Mindscape Software. "Sometimes you have very small C programs compiling to what seems to be a very large object," he says. "But what that's usually caused by is you've included a standard library of input/output functions with your object code even though your program may not actually use those." So if you're serious about keeping your finished C programs small, you want to avoid the automatic inclusion of a standard library. You can exclude any unused functions.

C's affinity with machine language gives the user greater programming power, but can also create big problems for novice programmers. Some programmers suggest that $C$ is best not attempted by

## A Sample Of C

Here is an example program which prints the numbers from one to ten and describes each number as odd or even. Program 1 is written in Amiga BASIC. By comparing it to Program 2, the C version, you can get a sense of some of the differences between the two languages. For one thing, C makes liberal use of braces- $\}$-to group statements into a compound statement, or block, which the language treats as a single statement. Functions are called by supplying the name of the function, with arguments in parentheses-the entire program is a function called main( ). Variables are declared before use, and comments are framed with /* and */ characters.

Program 3 is $C$ in a somewhat more condensed, but less easily visualized format. The IF-ELSE construct has been collapsed into one line using the conditional operator (?:) to designate the alternative results of the test. This brief sample, however, can't do justice to the qualities which make $C$ an increasingly popular language. There are several excellent texts on $C$ for beginners, available in most bookstores, which will give you a sense of the language's flexibility, power, and efficiency.

## Program 1:

REM This is a demo program written in AmigaBASIC
PRINT "The numbers from 1 to $10:$ "
FOR count $=1$ TO $1 \varnothing$
PRINT count;" ";
IF (count AND 1) $=1$ THEN PRINT "odd" ELSE PRINT "even"
NEXT count

## Program 2:

/* This is a simple demonstration of a C program, written for the Lattice $C$ compiler on the Amiga computer */
main()
\{
int count;
printf("The numbers from 1 to $10: \backslash n$ ");

```
    for (count = 1;count <= 10;count++)
```

    \{
        printf(" \%d ", count);
        if (count \& \(1==1\) )
            printf("odd \(\backslash\) n");
        else
            printf("even \(\backslash \mathrm{n}\) ");
    \}
    \}

## Program 3:

```
/* A more compact \(C\) version of the demo program */
main()
\{
    int count;
    printf("The numbers from 1 to \(10: \backslash n\) ");
    for (count \(=\varnothing\); ++ count \(<=1 \varnothing\);
        printf(" of ofs \(\backslash \mathrm{n}\) ", count, count \& 1 ? "odd" : "even"));
\}
```

# All the exciting, entertaining, and educational games, applications, and utilities from COMPUTE! magazine are now available on disk 

## for your Commodore, Atari, Apple, or IBM personal computer.

## The COMPUTE! Disk

A new COMPUTE! Disk is published every month, rotating among the four major machines covered by COMPUTE!: Commodore 64 and 128; Atari $400 / 800$, XL, and XE; Apple II-series; and IBM PC, PCjr , and compatibles.

Every three months you can receive a disk with all the quality programs from the previous three issues of COMPUTE! that will run on your brand of computer.

Like the popular COMPUTE!'s Gazette Disk, the COMPUTE! Disk is ready-to-load and error-free. It saves you valuable hours of typing time and eliminates typing errors.

With a subscription, you will receive one disk every three months for a total of four disks a year-for only $\$ 39.95$. That saves you $\$ 20$ a year off the singleissue cost.

Or you can order individual issues of the Disk for $\$ 12.95$ a disk plus $\$ 2.00$ shipping and handling.

Remember to specify your type of computer when ordering the COMPUTE! Disk. You'll find more information about this month's COMPUTE! Disk in this issue. (Note: You'll need the corresponding issues of COMPUTE! magazine to use the Disk since the disk will have no documentation.)

For fastest service when ordering a subscription to the COMPUTE! Disk, call toll free 1-800-247-5470 (in Iowa 1-800-532-1272).

For more details or to order individual issues of the COMPUTE! Disk, call our Customer Service Department toll free at 1-800-346-6767 (in New York 212-887-8525).
Please allow 4-6 weeks after placing an order for your first disk to arrive.

## This Publication is available in Microform.

people unfamiliar with machine language. At the very least, a disciplined, structured approach to $C$ programming is highly recommended.
'IIf you haven't done a lot of assembly language first, going from Pascal or BASIC to C is going to be more of a challenge because it is getting closer to the machine," says Jeff Steinwedel, engineering manager at Activision Software. "It's like going from BASIC to assembly language. You have to know a lot more about what's going on internally. The language system is going to be less help in bailing you out of a situation or preventing you from making bugs in the first place. But if you've done a lot of assembly language programming, the transition to C will be fairly straightforward."

One of the characteristics shared by $C$ and machine language is the ability to manipulate memory directly (in C, pointers are used). In higher level languages, memory access is often indirect. And C's heavy reliance on pointers is very powerful in general, says Hospelhorn.

But because you tend to do a lot of things with pointers, and because there's no error checking on pointers to see what they point to, you can wind up creating problems for yourself if you're not a disciplined programmer, he says. "It's possible to damage your program, to set memory locations that you didn't intend to if you're not well aware of where your pointers are pointing. That can make debugging sort of tedious. It's certainly possible for a programmer to generate very difficult errors-more so than some other languages that do a better job of checking things for you."

C, then, isn't a free lunch. What C gives you is a tremendous amount of power and flexibility, a feeling of liberation, he says, because most of the things you can think of, you can do in some way. But with that liberation comes a certain amount of responsibility. "It's always best to plan things out before forging ahead, but it might be a little more true in C."

And there's a big payoff after a C program is successfully completed and debugged: Translating that program to run on another 68000based computer is easier than transporting a program from, say, an

Apple II to an Atari 800. Part of the reason for this, of course, lies in the memory limitations of the eight-bit machines, "When you're in a very constrained machine without a lot of memory, like the Apple II, you tend to do a lot more in assembly language because you don't have the space," says Steinwedel. "With an Atari 1040 ST with a megabyte of memory, it probably isn't going to hurt you.
"But the real advantage is to be able to produce the code quickly and rapidly transport it from one environment to another. Something running in GEM on an IBM can move very quickly to the ST."

There's one additional reason for the popularity of $C$ on the 68000-based machines. It's often mentioned almost as an afterthought, but it's significant. There are currently many good $C$ compilers available. Other languages aren't as well-supported at this time with efficient, tested compilers. Lattice (Glen Ellyn, IL) and Manx Software Systems (Shrewsbury, NJ) publish C compilers that are enjoying popularity with 68000 -based computer programmers, as do several other software publishers. There are also versions of interpreted C available, for programmers who want to debug more easily. Some use interpreters to write the programs and then, after all the problems are ironed out, run the source code through a compiler for the greatest runtime efficiency.

Although the friendly user interfaces of the Apple Macintosh, Atari ST, and Commodore Amiga have enticed nontechnical consumers to purchase them as applications machines, sales of languages and how-to books and other programming utilities indicate that many buyers are planning to write their own programs. The special benefits of $C$ on 68000 machines recommend it to experienced machine language programmers. Likewise, people who have worked with higher level languages and want to move a bit closer to the inner workings of the computer might want to sample this special way of communicating with their machines. A decade and a half after its inception, the $C$ programming language is approaching a new level of popularity.

## The Top Five Free Programs For Your Computer

Arlan R. Levitan

Good software doesn't have to be expensive. You can accumulate a respectable software library merely by taking advantage of the thousands of programs in the public do-main-that is, programs which are given away free by their authors. Another alternative, the "shareware" concept, lets you test-drive a program for free and make a voluntary contribution if you like. Here's a guide to public domain software and shareware, plus the results of a survey in which users all over the country voted for their top five favorites.

Does the thought of paying more for a program than you laid out for your computer make you grumpy and irascible? Cheer up. There's a wealth of programs available for your computer that cost little or nothing at all. Public domain and shareware programs can provide you with a never-ending supply of grist for your computer's mill.

The idea of public domain software has been around since the early computer hobbyists first started sharing their programs with each other. People would try running each other's programs, suggest improvements, or make the improvements themselves. Few people copyrighted their programs because they were hobbyists rather than software authors trying to make a living. Legally, all it takes to place a program in the public domain is for the author to declare it so. (Of course, this excludes most programs published in magazines and books, which are nearly always copyrighted to protect the authors.)

Public domain programs can be freely exchanged between individuals or distributed by user
groups and computer bulletin board systems (BBSs). They come with no warranties, packaging, or customer support. They are gifts to the public and vary in quality from marginal to very good.

To determine which public domain programs are the most popular among users, in April we conducted a survey over three commercial information services: CompuServe, The Source, and Delphi. Below are the results of this informal survey. For each personal computer, we've listed the top five programs. The type of program is identified within parentheses.

We have excluded from consideration programs that are not truly in the public domain, including programs which elicit a fee for documentation, and programs which have been published, are in widespread use, but are definitely not in the public domain-such as compute!'s own SpeedScript, for example.

You'll notice that many of the popular programs on the list are terminal programs. This is probably due to the fact that the survey was conducted online among telecomputing enthusiasts.

To obtain copies of any of these programs, try contacting your local user group or logging onto a BBS or commercial information ser-
vice. Friends and coworkers are also valuable sources for public domain programs.

Another type of freely distributed software that is sometimes confused with public domain software is shareware (also called user-supported software). The concept of shareware came about as a response to the negative aspects of marketing software commercially.

It seems that almost everybody likes to complain that software is too expensive. Critics of the software industry claim that prices are inflated by a charge-what-the-market-will-bear attitude as the product filters through distribution channels. The manufacturer typically sells to a distributor, who in turn sells to a retailer. Each middleman adds a markup. The author of the software receives only a small percentage of the selling price.

Critics argue that this practice causes a serious problem: The perception of high prices encourages unauthorized duplication of software. This leads to a classic conflict between the manufacturers and the software pirates. Manufacturers may be tempted to boost their prices to make up for expected losses to piracy, and pirates may justify copying because they say prices are unreasonably high.

For these and other reasons, some software authors decide to market their programs themselves. There have been few success stories among those who've tried this approach. The authors attempt to work within the established marketplace, but usually fail because they lack the resources necessary to promote, advertise, and distribute their product.

About four years ago, a programmer named Andrew Fluegelman wrote a terminal program for IBM computers called PC-Talk III. To distribute his program, Fluegelman combined aspects of both public domain and commercial software to come up with a new category he called Freeware. Freeware is based on three concepts:

- Before buying a program, computer users should have the opportunity to fully assess its value by
using it extensively to determine whether it serves their needs.
- Original software of high quality written by independent authors will be supported by the personal computing community.
- Copying of these programs should be encouraged, rather than discouraged. The ease of disseminating programs outside traditional commercial channels should be exploited by software authors to maximize distribution.

Fluegelman actually trademarked the term Freeware, so as these ideas spread and other authors began following suit, the term shareware was coined for general use. Here's how shareware typically works:

Anyone can get a copy of a shareware program. Usually, you obtain it from a local user group or BBS. Since there is no packaging or manual, any documentation is generally in the form of a text file on the disk or BBS. You must print out a hardcopy if you want a manual for reference purposes.

Shareware programs contain a notice suggesting that you send a certain contribution to the author if you find the program useful. The contribution is voluntary, and even if none is made, you're encouraged to share the program with others.

Although no shareware authors are reported to be making a killing, many are said to be realizing a steady stream of supplemental income.

How good is shareware? The best of it is quite good indeed, and often better suited to the needs and abilities of casual users than more expensive commercial programs. If you're willing to do without fancy manuals and can rely on fellow users for technical support, shareware may be right for you.

Here are the top five freely distributed programs for each popular personal computer. Shareware programs are denoted with an asterisk (*). You'll notice that only four programs are listed for the Commodore $64 / 128$. That's because the other programs which received votes are not truly in the public domain-including two which are copyrighted by COMPUTE!.

You float high above a distant planet, controlling robot armies below. Can you take control of the priceless mining turf planetside, or will your opponent's robot crews prevail? To win at this thoughtfully designed, engaging strategy game, you'll need foresight and conceptual skills rather than a quick hand on the joystick. The original version is written for the Commodore 128. We've programmed new versions for the Commodore 64, Apple II series, IBM PC/PCjr, Atari 400/800/XL/XE, and the Amiga. A joystick is required to play the Commodore 128 and 64 versions. The IBM PC/PCjr version requires Cartridge BASIC for the PCjr and BASICA plus a color/graphics adapter for the PC. The Atari version requires a joystick and at least 48 K of memory. The Amiga version requires 512 K .
"Hex War" is a two-player strategy game that can be played five different ways, and there are limitless variations. But the basic premise is always the same: You and an opponent move armies on a field of hexagons, attempting to capture territory.

The goal of the first two games is simple: capture the capital city of the other player. In game 1, the capital cities are far apart; you must devote some of your armies to defending your own capital while attempting to breach the walls of the other capital. Game 2 puts the capitals near each other, so offense and defense tend to merge in this scenario. Most of the action takes place within a small area of the battlefield.

Games 3 and 4 spread the action over a wider area. In the third game, your object is to occupy eight
of the twelve cities on the game board. Six cities occupy the periphery, and six are in the center of the playfield. Game 4 requires actual control of six cities; you must have an army in the city, one that's not involved in a battle, before you're credited with control (this version will probably take the most amount of time to play).

Although the first four scenarios encourage a commitment to battle, you employ different tactics in the fifth. The goal here is to acquire 40 of the 61 hexes, so you need some free armies to move around. As soon as you claim 40 hexes, you win the game.

## Typing it In

Hex War is written in BASIC, with some important information in DATA statements. Type in the version for your computer and be sure
to save a copy. Refer to the notes below for special instructions specific to your computer. After the game has been saved, type RUN to begin playing.

When you first run Hex War, the computer pauses to set up the screen, then displays a menu of five choices. The five different games are explained in detail below. If you're new to the game, press the 1 key to choose game 1 . There will be another short pause while the variables are initialized, and then you'll see a playfield with 61 hex shapes, containing four armies on each side (see photos).

## Hexes And Hexadecimal

A chess board has 64 squares arranged in a rectilinear grid. Hex War gives you a playing field of 61 hexagons (almost as many as a chess board), but they're part of a six-sided honeycomb field. If you've played war games before, you may recognize the hexes.

If you're using a Commodore 128,64 , or Atari computer, plug in the joystick before playing (use port 2 for the 128 and 64). The other versions use keyboard controls as explained below. At first, the cursor movement may seem unusual. The cursor travels not up-down/leftright, but northeast-southeast/ northwest-southwest. To make the movement less confusing, turn your joystick 45 degrees clockwise, so that what was up becomes northeast, and so on.

Each hex has six neighbors, so an army can move in six possible directions. To travel left and right, you'll have to push the joystick twice (for example, up and right on the joystick to move one hex to the right, which counts as one movement).

Army strengths are listed in hexadecimal (base 16) numbers, so the four armies labeled 40 actually have strengths of 64 (the hexadecimal value 40 equals 64 in our everyday decimal numbering system). At the beginning of a turn, any army has exactly three movement points. It requires one point to move an army into a neutral or enemy-controlled zone. To move through the same zone also requires a point. To move into and through a friendly hex requires a total of one
point. This means you can move a single army through two neutral or enemy hexes in any one turn, but the same army can move through up to three friendly zones during a turn.

Select an army by moving the cursor onto it. Click the joystick button once, then position the cursor on a neighboring hex and click again. If you wish to stop, click again, and two plus signs $(++)$ will appear, signaling that no more movement can occur. Otherwise, position the cursor on another neighboring hex and click.

## Zones Of Control

Each army controls the six contiguous hexes surrounding its resident hex. If you enter an enemy's zone of control, you forfeit any additional moves and must prepare for battle. In addition, an army that begins the turn in a zone of control cannot move until the battle is resolved.

## Robots Vs. Robots

In this game, you aren't really on the planet, but parked high above it in a remote mothership. You've landed some robots to explore the area, and they've encountered robots belonging to another explorer. Your robots, or bots as you call them, follow your orders to advance toward the other bots. Each bot has a mining laser which can stop or disable the other bots. Also, your bots have disruptor beams which can daze another bot, temporarily confusing it. When two bot-groups come close to each other, they shoot lasers and disruptors until one army of bots is disabled.

Three things can happen to a robot which suffers a hit. If the robot suffers a direct hit in its logic unit by a laser, it is vaporized. It is destroyed forever and never reappears in play.

The second thing that can happen is injury. If the laser beam is deflected, the robot is out of commission until it can be transported back to a botspital. An injured bot is frozen in place until the battle is finished, after which the victorious army carts away the injured bots to be repaired and reused.

Thus, winning a battle means you evacuate both the friendly injured and the enemy injured. After
all of the injured bots recover, they join the force in whose botspital they were healed. In effect, injured bots eventually become members of the army which won the battle in which they were damaged.

The third possibility is confusion: The robot is temporarily disoriented for two turns. When the time has passed, the robot is ready again.

## Reprogramming Bots

Moving the cursor onto an army of robots brings up a status window in the upper-left corner of the screen. The number in reverse video is unimportant; it's the army number (which may change as the game progresses).

The four numbers underneath are significant, however. The first is the army's active strength (in deci$\mathrm{mal})$. The second is the number of injured robots, which will be transported to the botspital of whichever side wins the battle. The third-on the line below-is the number of disrupted robots who will be available for combat in the next turn. The fourth number is how many robots can join the active force two turns from now.

If one side is able to reduce the other player's active force to zero, two things happen. The winner sends all injured bots away to be repaired. The winning side also collects all enemy bots (injured or dazed) and sends them to the reinforcement center to be reprogrammed. Eventually all these bots will available to the winner of this particular battle for future engagements.

## Reinforcements <br> And Mergers

At the start of the game, you'll see some armies positioned outside of the hex field. These are reinforcements and reserves in transit to the battle. Player one's reinforcements enter at the bottom right corner; player two's enter at the top left. The line of new armies moves counterclockwise; the army next to the entry point is the next to enter the battlefield.

However, the reinforcements cannot enter the battlefield if an army (friendly or enemy) is blocking their way. Keep your armies off

your own reinforcement point, and try to block your opponent's armies from this area if you can. If the entry hex is owned but not occupied by your opponent, you'll lose some reinforcements.

After completing a turn, you are credited with additional reinforcements according to how much territory you own. Passing over a hex allows you to claim it; the hex changes color to indicate ownership. Each piece of property provides enough ore and energy to build a new robot, available for use two turns in the future. The numbers in the line of reinforcements. are updated after you move to show additional robots being built.

Winning a battle also provides additional armies in the line of reinforcements. As mentioned above, a victorious army captures any dazed enemy bots, which are reprogrammed and available in three turns. At the same time, the winner evacuates injured bots of both sides. Transportation and repair take five turns for friendly bots, seven for enemy bots. The two additional turns are needed for reprogramming the opponent's forces.

If you're losing a battle, the number of injured robots (displayed in the status window) will begin to rise. Remember that, if your opponent reduces your active strength to zero, he or she will capture all of your injured bots; they'll be reprogrammed and added to future reinforcements. To prevent this from happening, you're allowed to bring in a second army for merging. Simply move another army on top of the army with which you want to merge. There's just one rule: One or both of the armies must have a strength less than 32 decimal ( 1 F or less in hex).

## Customizing The Scenarios

The five built-in scenarios provide plenty of variety, but if you'd like to add more challenges, here are some suggestions. (The following line number references are for the 128 version of Hex War, Program 1; other versions may differ slightly, although the variable names are the same in most versions.)

First, a note about the logical organization of the grid. The vari-

The Commodore 128 version of "Hex War," an absorbing strategy game with many variations.

"Hex War" for the Commodore 64.

"Hex War" For Atari 600XL, 800, 800XL, 1200XL and 130XE

Apple II "Hex War."
ables T and $\mathrm{B}, \mathrm{CT}$ and CB , and HT and HB are used to locate the coordinates on the playing field (see figure). The first number is T (or HT or CT), the second is B (or HB or CB). These coordinates are also used in the three-dimensional MAP array (where level 0 of the array is the army number, 1 is the current owner and 2 keeps track of whether or not a city is located there); they're also part of the ARMY array. By varying the starting position, number of armies, reinforcement strengths, and location of cities, you could simulate historic battles.

To add or subtract cities from the field, change the value of CN in line 50. You'll also have to change the DATA statements in lines 270 and 280 . The numbers there are the T and B coordinates of the cities.

The strengths and locations of the armies can be changed as well. The DATA statements starting at line 1540 determine the strength (64) and T/B coordinates for the armies at the beginning of the game. If you wish to start with more armies (or fewer), you'll have to change the inner FOR-NEXT loop
(with the index of $K$ ) in line 1500 . In that same line, change $N X(J)$ to one number higher than the number of armies on each side. For example, if you want six armies apiece, change NX(J) to 7. The subroutine at line 1600 sets up the reinforcements; if you don't like the random patterns, change the formula here.

Variables defined in lines 70-90 control the play of the game. PN determines which player goes second; it can be either zero or one. Variable ME controls the maximum merge strength. If you'd like to be able to merge any two armies, change it to a high value ( 512 , for example). To remove the merge option altogether, change ME to zero.

The movement points are defined by MM in line 80 . Movement across friendly territory takes one point, across neutral or hostile territory two points. Increasing MM will give your armies more mobility. The three variables KA, KB, and KC affect the outcome of individual battles. KA determines how many bots are vaporized, KB controls the number injured, and KC affects how many are dazed. If you make the fractions smaller ( $1 / 24$, for

example), the battles end more quickly. The subroutine starting at line 2600 resolves current battles.

## Commodore 64 Version

The 64 version of Hex War (Program 2) looks and plays exactly like the original 128 version. However, one additional step is needed before you run the game. After you have typed in the game and saved it on disk or tape, type this line in direct mode (without line numbers):

## POKE 44,64:POKE 64*256,0:NEW

Be sure to press RETURN after you type the line. Now load and run the program as usual. It is very important that you perform this step before running the program: If you don't, the screen will be jumbled and impossible to decipher.

You may find it easier to let the 64 handle this chore for you. Program 3 is a short loader which performs the setup, then loads and runs Hex War. To use the loader, you must have Program 2 saved with the name HEX WAR on the same disk or tape as Program 3 (for tape, Program 2 must follow Pro-
gram 3 on the tape and the $\mathrm{DV}=8$ in line 10 of Program 3 must be changed to $\mathrm{DV}=1$ ).

## Atari Version

In the Atari version (Program 4), armies are maneuvered using a joystick plugged into port 1. Joystick controls are the same as described above for the 128 version.

This version generates extra colors in graphics mode 0 using a technique known as artifacting. However, the resulting colors may vary on different Ataris, so a small change may be required. The game should start with the red army at the top of the screen and the blue army at the bottom. If that is not the case on your machine, change the following line:

ND 4 977 RESTORE 414 : FOR $A=C$ HSET+24ø TO CHSET+24 7: READ B: POKE A, B:PD KE A+8, B\&2: NEXT A: RE TURN

If the colors are not corrected, the machine may appear to declare the wrong side the winner at the end of the game.

## Apple Version

Program 5 is for all Apple II-series computers using either DOS 3.3 or ProDOS. To get the full benefit of the detailed high-resolution graph ics, a color monitor or color TV is recommended. (The program incorporates the HROUT high-resolution graphics routine from the "Apple Superfont" article in the April 1985 issue to generate these graphics.)

Use keyboard controls to maneuver armies in this version. Press the period (.) key to go northeast (use the $>$ symbol on that key as a reminder), the comma (,) key to go northwest (note the $<$ symbol on that key), the $\rightarrow$ to move southeast, and the + key to move southwest. Use the space bar to select or set an army. Press RETURN to end your turn before all your armies have been moved. A player indicator appears in the lower-right corner to indicate which player has the current turn.

## IBM PC/PCjr Version

Like the Apple version, the IBM PC/PCjr version of Hex War (Pro-

The IBM PC／PCjr version of＂Hex War．＂

＂Hex War＂for the 512K Amiga．
gram 6）uses keyboard controls in－ stead of a joystick．Press cursor－up to go northeast，cursor－right to go southeast，cursor－down to go southwest，and cursor－left to go northwest．If you can turn the key－ board 45 degrees in a clockwise direction，these directions will seem more natural．

Use the space bar to select or set an army．Press ESC to end your turn before all your armies have been moved．A player indicator ap－ pears in the lower－right corner to indicate which player has the cur－ rent turn．

## Amiga Version

The Amiga version of Hex War （Program 7）requires 512 K of mem－ ory and is written in Amiga BASIC （not the ABasiC which was shipped with early Amigas）．Before you start typing the program，notice the small left arrows at the end of each program line in the listing．These indicate the end of each program line，and are not intended to be typed（in fact，we deliberately chose a character that＇s not available on the Amiga keyboard）．Instead， press RETURN wherever you see a left arrow in the listing．

This game uses exactly the same keyboard controls as the IBM PC／PCjr game（see above）．Move the cursor on the playfield with the cursor keys，and press the space bar to pick up or set an army．Your turn ends when all your armies have moved or when you press ESC．

Amiga Hex War includes syn－ thesized speech to emphasize vari－ ous events and provide information during the game．For instance， when you select an army，the com－
puter tells you the number（in deci－ mal）of robots in that army．If you＇re not familiar with hexadeci－ mal numbers，this feature can help you learn hex notation．

Either player can turn the speech off or on at any time．Simply click the mouse button twice：A small window appears and the computer announces the current voice status．If speech was previ－ ously activated，it now shuts off， and vice versa．Click the mouse button once to erase the window and resume play．A similar window appears to announce the outcome at the end of each game．

For instructions on entering these listings， please refer to＂COMPUTEI＇s Guide to Typing In Programs＂in this issue of COMPUTEI．

# Leader Board For The 64 

David Florance
Programming Assistant
Requirements: Commodore 64 (or Commodore 128 in 64 mode) with a disk drive and a joystick. Versions for the Amiga and Atari ST are planned.

The spring and summer months, with their profusion of golfing events, couldn't be a better time for Access Software to have released its new Leader Board professional golf simulator. Continuing in the tradition of such earlier popular releases as Beach-Head and Raid Over Moscow, Access has fashioned a stunning piece of software in this new golfing game.

All who have tested Leader Board agree that it has excellent sound and graphics and is a lot of fun to play. Leader Board is easy to use, too. Although you probably won't shoot un-der-par scores during your first 18 holes, we've yet to see someone play the game and not like it. One person trying Leader Board for the first time scored a 52 on one hole (for you golf novices, that's not very good), and still said he enjoyed the game. Another player, professing to like neither computers nor golf, is considering buying a computer just to play Leader Board.

Bruce and Roger Carver, authors of the game, have done an exceptional job on everything from the golfer's swing to the action of the joystick. The program lets you hook, slice, cut, plug, top, and drub-just as in real life. You can even learn to hit the ball straight-if you concentrate.

Leader Board offers three levels of play: novice, amateur, and professional. Start with the novice level to get some practice. You can even move to the driving range for additional practice on your strokes. The program lets you play anywhere from 18 to 72 holes, and there are four courses from which to choose-each with a distinct personality and level of difficulty. Even the

Teeing off on a typical hole in Leader Board, an exceptional golf simulator for the Commodore 64.
wind is a big factor on the professional level of Leader Board.

## Good Whooshes And Plops

From one to four players can take part, and scoring is automatic. The sound effects-from the whoosh of the stroke to the plop of the ball landing in a water hazard-are excellent throughout. Even the sound of the ball dropping into the cup is realistic. The movements of the golfer and the ball in flight (and bouncing on the fairway or green) are superb.

Just as in a real game of golf, you'll need some time to get your strokes down. You control the power of your swing and the direction of the ball by pressing the joystick button and moving the stick forward or backward at the right moments.

After playing hundreds of holes, I've concluded that the most important factor in making good scores is selecting the right clubs. Leader Board's manual offers course cards with detailed yardage indicators as well as a chart with normal club distances. These are invaluable. Access Software is also selling additional tournament disks, with four different courses on each disk, for $\$ 19.95$ each.

The Leader Board disk is not copyprotected, so you can make backups for safekeeping. None of the disks work, however, unless a security key is plugged into the computer's cassette port.

I've been a golfer for about 15 years. Maybe it's a coincidence, but
when I went to my local course after playing Leader Board for several weeks, I had a great round. Who knows? Maybe Leader Board is even improving my game.

## SunDog: Frozen Legacy For Atari ST

David Florance<br>Programming Assistant

Requirements: Atari ST-series computer with a color monitor; or an Apple II-series computer with at least 64 K RAM and a color monitor. The ST version was reviewed.

Certainly one of the most exciting aspects of the future is space exploration. How will it be out there? What will we find, and how will we learn to adapt and go about our everyday existence? Will people carry the same instincts, societal norms, beliefs, and habits into the dark reaches of space? Whatever happens, it's a sure bet that if life's at all similar to SunDog: Frozen Legacy, we'll still have to know what's a good deal and what's not, when to beg, when to borrow, and when to...well, rethink our priorities.

SunDog, from Oasis/FTL games, is a first-rate graphics adventure with enough complexity for the seasoned player but simple enough for a beginner to enjoy. First marketed for the Apple II computers, the new Atari ST version features stunning graphics and easy mouse-driven controls.

You start this adventure with a tremendous inheritance left to you by an ambitious uncle who had designs on building a religious colony. Your task, a large one, is to fill his shoes by completing his dream. It's not easy. There's
more than one obstacle in your path. You don't know where the colony was planned, how to pilot a freighter (the SunDog), or how to spend the money he left you. Be careful-chances are you'll be mugged, swindled, and/or lost in a vast mountainous continent before you know it. You can even lose your starship and your inheritance if you don't pay attention to business.

Your first task is to find the colony (named Banville). There's an immense amount of ground to cover because SunDog: Frozen Legacy encompasses 50 cities on 18 different inhabited planets in 12 star systems.

Next, you'll have to locate and buy all the goods necessary to complete the colony. Although you start off with enough money to purchase the goods, unless you are very adroit, lucky, or both, you'll make some financial mistakes that may exhaust or at least severely deplete your bank account. Don't despair. Just start over and be more careful next time. Remember, no one promised that life in the far reaches of space would be a rose garden.

## Beware Of Beggars

Interaction is an important part of SunDog: Frozen Legacy. The shopkeepers and store managers talk to you, and you're expected to respond. Your range of possible responses is limited, though this might be fortunate. If you utter the things that run across your mind while you're trying to finish the mission, you'd probably be hunted down by the galactic security force and executed on sight. So don't be too abrasive.

On the other hand, when a beggar asks you for money, don't give him your last piece of cash. You may need it to transport hastily out of the city. Some of those beggars are ruffians as well, so be prepared to defend yourself. In other words, even in this futuristic setting, the general populace seems still to agree with P.T. Barnum's dictum that a sucker's born every minute. And for the most part, you are considered the latest.

Other characters to watch out for are the many entrepreneurs wandering around or hanging out in the eating establishments. They're more than willing to be your pal. You'll have to be clever to sort out the good and bad deals. These gents can help you as well as harm you.

## Popsicle People

To finish the adventure, you have to locate the colonists. They aren't capable of finding you because they're cryogenically frozen. This is when your piloting skills aboard the SunDog are put to the test. Setting the course is perhaps the

A top view of the SunDog, a space freighter in which you search for frozen colonists and a lost colony (Atari ST version).
most challenging level of the adventure. There are many ways to be successful, and just as many ways to fail. For instance, you can save time by traveling at warp speeds, but you'll spend more fuel, and trying to reach warp can be dangerous. To be safe, be sure to check for engine damage often. When the SunDog is not operating at peak efficiency, you lose time and effort. Buying replacement parts is not difficult, and if you shop around you may
be able to find some bargains.
The Atari ST gets a chance to show off with SunDog: Frozen Legacy. Stunning visual effects abound, and each level has graphic screens that will amaze you. The detail is enormous. If you've been wondering what a graphics adventure game is like on the new generation of personal computers, SunDog: Frozen Legacy is a must. It's a whole different world.

A helpful hint from this Star Freighter Captain. Don't let your eyes fool you. You must still eat and sleep to survive and complete the mission. So take time out to catch a few winks and grab a bite to eat. You'll need all your strength and attention to conquer the challenges of SunDog.

## The Goonies And Zorro

Karen McCullough

Requirements: The Goonies-an Apple II-series computer with at least 48 K RAM and a disk drive; Commodore 64 or 128 (in 64 mode) with a 1541 disk drive; or an Atari 400/800/XL/XE with at least 48 K RAM and a disk drive. Zorro-same requirements, except Apple II-series computers must have at least 64 K RAM. Color monitor optional but recommended. Joystick required. The Apple versions were reviewed.

Are you tired of shooting aliens and centipedes in arcade-style computer games? Bored with piloting helicopters and drilling holes in brick walls? Does it seem like you've done it all-dodged the best of them, shot the worst-so that it's all a bit of a drag now? Don't give up yet. Datasoft/IntelliCreations has some new challenges for you: games with a smooth blend of arcade action and adventure-like puzzle-solving.

Help the Goonies (that famous band of adventurers from the movie of the same name) negotiate an underground labyrinth to find pirate treasure and save their parents' home from foreclosure. Or perhaps you'd rather be Zorro, using cunning and a sharp sword to rescue a lovely princess from Sergeant Garcia.

Whichever fantasy you choose, you'll need the standard arcade equipment: a keen eye and quick reflexes. But in these games, there's more to negotiating an underground maze than jumping over cannonballs and dodging bats. What do you do about steampipes that block your path? And how can you scale new heights without a ladder? If you consider it unreasonable to have to think about a problem rather than shoot your way out, you'd better consider another game.

Still interested? Good. These two games have a lot to recommend them: excellent graphics and animation; smooth, fast screen changes; and accurate control. At the start of each session with the Apple version, the program asks you to calibrate your joystick by moving the stick to the right-, left-, top-, and bottommost positions. Thereafter, the game adjusts itself to your stick settings, resulting in control as tight and as precise as found in most coin-operated videogames. (Joystick calibration isn't necessary with the Commodore and Atari versions.)

## Inventive Puzzles

One of the best features of these games is their interesting and inventive puzzles. There's a lot happening on each screen, and it may take some time to figure out what it all means. In The

Goonies, the solution to a problem often requires getting the two characters on the screen to cooperate. In Zorro, you may need a special object, lots of curiosity, or just a bit of luck to solve a puzzle.

The two games are similar in concept, but not identical in execution. The Goonies has a stronger arcade action feel, as befits its descent from that exciting (if not very memorable) movie. Zorro plays more like a graphic adventure. There are objects to collect (some may have magical properties), a town to map, secret passages to find, and visual puzzles to solve. The Goonies has a hint sheet to help you figure out solutions; in Zorro, you're on your own.

Good as they are, though, neither game is perfect. Zorro could benefit from a hint sheet of its own-even with a good-quality color monitor it's difficult to tell what some of the objects are. One screen has something that looks like (but surely isn't?) a Coca-Cola bottle. A lantern, perhaps? A club? We aren't sure.

The Goonies needs a way to allow a player to practice on upper-level screens without going through all the lower ones. It takes some 20 minutes of playing time to get to the last levels; you arrive with only one or two lives left and promptly get zapped. That's acceptable at an arcade where the real
object is to entice you to spend another quarter, but in a home computer game, it can be frustrating. It would be nice to have an option similar to the one in Lode Runner which allows you to play on any level you wish, but prevents you from setting an official high score without progressing through the levels in proper order. Of course, high scores aren't much of a consideration in The Goonies or Zorro, since neither game saves these scores-another minor flaw.

One final quibble concerns the lack of an option for keyboard control, particularly in the Apple version. Many a white-collar computer runs games during lunch hour, but wouldn't dare be caught with anything so unprofessional as a joystick hanging out of its side. Most Apple games have a keyboard option for this reason.

Overall, however, The Goonies and Zorro are attractive games-fun, interesting, and entertaining. Due to the level of difficulty, they're not appropriate for children under ten, but older kids and adults will have a good time with them.

# Moebius: The Orb Of Celestial Harmony For Apple 

James V. Trunzo

Requirements: Apple II-series computer with at least 64 K RAM and a disk drive. Commodore 64/128 version scheduled for release by July.

Fresh on the heels of the celebrated release of Ultima IV, Origin Systems has produced yet another program worth raving about. Moebius: The Orb of Celestial Harmony capitalizes on the current popularity of ninjas by casting the player as a youthful martial arts disciple on a trip through an oriental world full of danger and excitement.

Moebius combines all the familiar elements of a computer role-playing game with an arcade-style combat system that's both challenging and functional. That is, the arcade-style combat wasn't included merely to show off the program's superior graphics. Your ninja disciple must become proficient with both a sword and his bare hands to defeat enemies and gain experience points that heighten various attributes.

The theme of Moebius is simple. After learning all he could from his ninja masters, a wayward disciple named Kaimen stole the Orb of Celestial Harmony. This act has brought much suffering to the land of Khantun. Kaimen has set himself up as supreme warlord and is conducting a reign of terror. He has imprisoned the Holy Ones, replacing them with his own evil monks. Monsters roam the land and infest the waters of Khantun. A savior is needed-a warrior who has devoted his life to Moebius and who has trained with the Sword Master, the Martial Arts Master, and the Zen Master (for all is not won through force of arms). You are that savior, the ninja warrior.

## Protect Your Karma

Moebius employs a number of singlekeystroke commands, much like other Origin games such as Ultima and its sequels. Your commands are varied: You can communicate with the many characters you encounter during your travels (even the skeletons of the victims of Kaimen-if you know magic),

A typically ominous screen from Moebius: The Orb of Celestial Harmony.
swing your sword to cut vegetation that blocks your way, use an item in your inventory, throw a shuriken, and much more.

The game is made even easier to play by the use of windowing. Windows often pop up on the main screen to offer various options. For example, pressing the $C$ key to communicate opens a window and gives you the choice of asking a character for help, to follow you, to stay and wait for you, or to go away.

Much thought is required to play Moebius well. The mystery and intrigue of the Orient permeate the game, and virtuous behavior is often rewarded. You must think of others before yourself to be successful and preserve the purity of your Karma (very important).

Furthermore, strategy, planning, and quick thinking are a must. Poor villagers are afraid of men carrying swords and are averse to helping them; yet, hungry tigers cannot be fought off with your bare hands. It's up to you to decide when to arm yourself and when to trust in your karate skills.

## Tiger Teeth And Panda Hair

The realm of magic is not ignored, either. In Moebius, however, magic works a little differently than in dungeon adventure games. Magic requires a strong mind, so you must fast and chant special mantras to activate such spells as Speak with the Dead, Waterwalk, or Cure Sickness. Likewise, your mind must be clear to divine the nature of artifacts. When this magic is combined with another component (tiger teeth, beetle pincers, condor feathers, etc.), you can teleport, use ventriloquism, cause paralysis, and invoke many other charms. Incidentally, the magical components must be found and then either purchased or earned. To get panda hair, for example, you must first trap the bear.

Moebius embodies its own unique playing style and feel, and it gives the player an unmistakable sense of the Far

East and Zen philosophy. As a programming effort, it equals anything on the market today: graphics are topnotch, ranging from full-screen images to highly detailed temples; onscreen instructions and help are easy to use and aid in play; and the challenge of solving Moebius ensures many hours of enjoyment as you travel through the realms of Earth, Water, Air, and Fire to find and reclaim the Orb of Celestial Harmony.
Moebius: The Orb of Celestial Harmony Origin Systems, Inc. Distributed by Electronic Arts 2755 Campus Drive San Mateo, CA 94403 $\$ 59.95$

# COMPUTE's Author Guide 

Most of the following suggestions serve to improve the speed and accuracy of publication. COMPUTE! is primarily interested in new and timely articles on the Commodore 64/128, Atari, Apple, IBM PC/PCjr, Amiga, and Atari ST. We are much more concerned with the content of an article than with its style, but articles should be clear and well-explained.

The guidelines below will permit your good ideas and programs to be more easily edited and published:

1. The upper left corner of the first page should contain your name, address, telephone number, and the date of submission.
2. The following information should appear in the upper right corner of the first page. If your article is specifically directed to one make of computer, please state the brand name and, if applicable, the BASIC or ROM or DOS version(s) involved. In addition, please indicate the memory requirements of programs.
3. The underlined title of the article should start about $2 / 3$ of the way down the first page.
4. Following pages should be typed normally, except that in the upper right corner there should be an abbreviation of the title, your last name, and the page number. For example: Memory Map/Smith/2.
5. All lines within the text of the article must be double- or triple-spaced. A one-inch margin should be left at the right, left, top, and bottom of each page. No words should be divided at the ends of lines. And please do not justify. Leave the lines ragged.
6. Standard typing paper should be used (no erasable, onionskin, or other thin paper) and typing should be on one side of the paper only (upper- and lowercase).
7. Sheets should be attached together with a paper clip. Staples should not be used.
8. If you are submitting more than one article, send each one in a separate mailer with its own tape or disk.
9. Short programs (under 20 lines) can easily be included within the text. Longer programs should be separate listings. It is essential that we have a copy of the program, recorded twice, on a tape or disk. If your article was written with a word processor, we also appreciate a copy of the text file on the tape or disk. Please use high-quality 10 or 30 minute tapes with the program recorded on both sides. The tape or disk should be labeled with the author's name, the title of the article, and, if applicable, the BASIC/ROM/DOS version(s). Atari tapes should specify whether they are to be LOADed or ENTERed. We prefer to receive Apple programs on disk rather than tape. Tapes are fairly sturdy, but disks need to be enclosed within plastic or
cardboard mailers (available at photography, stationery, or computer supply stores).
10. A good general rule is to spell out the numbers zero through ten in your article and write higher numbers as numerals (1024). The exceptions to this are: Figure 5, Table 3, TAB(4), etc. Within ordinary text, however, the zero through ten should appear as words, not numbers. Also, symbols and abbreviations should not be used within text: use "and" (not \&), "reference" (not ref.), "through" (not thru).
11. For greater clarity, use all capitals when referring to keys (RETURN, TAB, ESC, SHIFT), BASIC words (LIST, RND, GOTO), and three languages (BASIC, APL, PILOT). Headlines and subheads should, however, be initial caps only, and emphasized words are not capitalized. If you wish to emphasize, underline the word and it will be italicized during typesetting.
12. Articles can be of any length-from a singleline routine to a multi-issue series. The average article is about four to eight double-spaced, typed pages.
13. If you want to include photographs, they should be either $5 \times 7$ black and white glossies or color slides.
14. We do not consider articles which are submitted simultaneously to other publishers. If you wish to send an article to another magazine for consideration, please do not submit it to us.
15. COMPUTE! pays between $\$ 70$ and $\$ 800$ for published articles. In general, the rate reflects the length and quality of the article. Payment is made upon acceptance. Following submission (Editorial Department, COMPUTE! Magazine, P.O. Box 5406, Greensboro, NC 27403) it will take from four to eight weeks for us to reply. If your work is accepted, you will be notified by a letter which will include a contract for you to sign and return. Rejected manuscripts are returned to authors who enclose a self-addressed, stamped envelope.
16. If your article is accepted and you have since made improvements to the program, please submit an entirely new tape or disk and a new copy of the article reflecting the update. We cannot easily make revisions to programs and articles. It is necessary that you send the revised version as if it were a new submission entirely, but be sure to indicate that your submission is a revised version by writing, "Revision" on the envelope and the article.
17. COMPUTE! does not accept unsolicited product reviews. If you are interested in serving on our panel of reviewers, contact the Review Coordinator for details.

# Screen Handler 64 

Jeffrey Bailey

This useful utility adds some word processor-like features to the Commodore 64's full-screen editor for use within your own BASIC programs. It also works on the Commodore 128 in 64 mode.

Although it's often taken for granted, the Commodore 64 has one of the best full-screen editors in the business. You can easily move the cursor anywhere on the screen, type characters, and make changes wherever you like. Not all computer owners are so lucky.

As good as it is, however, there are some things that the Commodore 64's excellent screen editor can't do. If you were to draw up a wish list for a new screen editor that would be active when a BASIC program requests keyboard input, it might include these features:

- Switchable insert mode.
- Delete key that draws text into the cursor.
- Key to move the cursor to the beginning of input.
- Key to move the cursor to the last character typed.
- Key to erase text from the cursor to the end of the line.

That's quite an impressive list, but there's one more feature that's also desirable: a special key to clear out a single field. In this context, a field is simply a screen area of a
certain size in which the user can type characters. For instance, let's say your BASIC program needs to request the date in the format mm/dd/yy. Each two-digit entry could be defined as a field that's two characters in length. Ideally, the user wouldn't need to type the / character between each field. As each two-digit entry was completed, the cursor would move automatically from the end of one field to the beginning of the next.

To take this concept even further, how about setting up multiple fields at different spots on the screen? If each field works as we've described, it wouldn't be necessary to press RETURN after typing data in each field. During the entry process, the user could move freely from field to field until each one is filled in. Then your program could read the entire screenful of data at once.

It may sound like a tall order, but "Screen Handler 64" makes all of this possible.

## Entering The Program

Although Screen Handler 64 is written completely in machine language, no knowledge of machine language is needed to use it. To type in Screen Handler 64, simply use the "MLX" machine language entry program listed elsewhere in this issue. Follow the MLX directions carefully. Here are the addresses you need for MLX:

Starting address: C000
Ending address: C397
You can then begin entering the Screen Handler data from Program 1. When you finish entering all the data, be sure to use the MLX Save option to store at least one copy on tape or disk.

To load Screen Handler into memory, use LOAD"filename", 8,1 for disk or LOAD" filename", 1,1 for tape. Although Screen Handler is less than 1 K in length, it uses all of the free memory from locations 49152-53247, so you shouldn't do anything to change those locations while the program is active. In addition, you should avoid changing the contents of memory locations 251-255, which Screen Handler uses as well.

## Starting Screen Handler

It's quite simple to incorporate Screen Handler into your BASIC programs. After the machine language is in memory, set up a table of the fields you want, then call Screen Handler with a SYS command. Screen Handler takes care of everything else, including moving the input data into string variables. Getting started is actually a threestage process. Let's look at each one in turn.

The first step after loading Screen Handler is to include the statement SYS 49152 in your BASIC program. This statement, without any extra parameters,
clears the field table that Screen Handler uses internally.

The next step is to set up each individual field, a job that's also done with a SYS. Here's the general format for the command:

## SYS 49155, $x, y$,length,string $\$$

Notice that this SYS statement is followed by four parameters. The first two, $x$ and $y$, stand for horizontal and vertical screen locations, and can be either numbers or numeric variables. The $x$ value must be in the range $0-39$, and $y$ must be in the range $0-24$.

The next parameter, length, defines the length of the field in characters. The length parameter can be any numeric value from 1-254. However, keep in mind that the field must not be so long that the screen scrolls when data is typed. If this happens, Screen Handler can't read the input correctly (because the data has moved up one or more lines).

The final parameter, string $\$$, can be any type of string variable, from a simple string such as A\$ to an array element like FI\$(6). Multidimensional arrays like FI\$ $(8,2)$ can also be used. Screen Handler automatically takes the information from the screen and puts it into this string variable. Note that if the input data is shorter than the field length (if the user types DOG in a ten-character field, for instance), Screen Handler fills the remainder of the string with spaces.

Once you've defined a string within a Screen Handler field, you should not redefine the string until after Screen Handler has been called (see below). This is because Screen Handler sets up pointers to BASIC's string storage space. If you suddenly redefine a string, it may move in memory, confusing the program. After Screen Handler has been called and input has been entered from the keyboard, it is safe to modify the string.

## A Better Way To INPUT

Screen Handler permits you to define as many as 50 different fields. When all of the fields are set up, it's time to call Screen Handler. The statement SYS 49158 tells Screen Handler to begin receiving input from the fields you have defined.

At this point, the up and down cursor keys move the cursor from field to field, not from line to line as usual. The RETURN key has the same effect as cursor down, moving you forward (down) to the next field. The left and right cursor keys work normally, but only within a field. That is, these keys move the cursor left and right inside the field as usual. But to move to another field, you must press cursor up/ down or RETURN.

Pressing CLR/HOME moves the cursor to the beginning of the current field. SHIFT-CLR/HOME erases the field and homes the cursor. The INST/DEL key works normally, but acts only on the current field. The CTRL-I key combination (hold down CTRL and press I) switches Screen Handler in and out of insert mode. The border color changes to indicate when insert mode is active.

Pressing CTRL-D deletes text by pulling it into the present cursor position. CTRL-E erases every character from the cursor to the end of the field. To move the cursor to the last character typed in a field, press CTRL-N.

That takes care of the entire wish list except for the most important part-storing all of the input data in variables. When all of the data is entered in all of the fields, press SHIFT-RETURN. Screen Handler enters the entire screen at once.

## Practical Demonstration

Program 2, "Screen Handler Demo," is a simple BASIC program that illustrates how to use Screen Handler. Here's an explanation of how it works.

Line 10 loads Screen Handler from disk, and lines 20-60 create a screen display that outlines the fields visually. The DATA statement in line 70 contains $x, y$, and length values for defining the fields. Line 90 clears the field table and prepares Screen Handler for use. Lines 100-140 set up a simple loop to read in the values and set them up in Screen Handler's table.

Note that although an array is used in line 130, the program contains no DIM statement. If BASIC encounters an array that was not previously dimensioned, it auto-
matically dimensions the array for 11 elements (numbered 0-10). Since Screen Handler uses some of BASIC's built-in routines, this feature is available as usual. However, it would be better programming practice to explicitly dimension the array variables-and the DIM is required if you want to use more than 11 array elements. In this case, the DIM statement must precede the SYS 49155 statement that assigns the array element to a field. In Program 2, the DIM statement could be placed anywhere before line 100.

Line 160 tells Screen Handler to start accepting data. Again, notice that the string variables must not be modified between the time that the fields are defined (line 130) and Screen Handler is called (line 160). Once the data has all been entered and you press SHIFT-RETURN to accept the fields, lines 170-210 clear the screen and print out the information. At this point in the program, it becomes safe to modify the string variables if needed.

With a little bit of practice, you can write very professional programs in BASIC with Screen Handler's help. Experiment with programs of your own.

## Program 1: Screen Handler 64

# Atari Sound <br> Development System 

Michael Ryder

This versatile program lets you design sounds onscreen with a joystick and the keyboard, taking advantage of virtually every feature built into the Atari's sound chip-including some features which are rarely exploited. The custom sounds can then be saved on disk, played back, or added to your own BASIC programs. For all Atari $400 / 800, X L$, and XE computers with at least 40K RAM and a disk drive.

Ever since the Atari was first introduced in 1979, its sound capabilities have always played second fiddle to its graphics. In fact, even many Atari owners are unaware that the sound chip inside their computer has switchable high-pass filters, optional 16 -bit frequency resolution, and an adjustable clock rate for modifying the frequency range. Part of the problem is that Atari BASIC's SOUND statement doesn't begin to touch these capabilities; they're accessible only with PEEK and POKE or machine language.

The three programs included here, collectively known as the "Atari Sound Development System," make it easier for you to take advantage of these features-or get acquainted with them in the first place. The main program, "Sound Editor," is a utility that puts the full range of Atari sound capabilities at your command with keyboard and joystick controls. It also lets you design sounds with ADSR enve-lopes-a feature that, as we'll see in a moment, isn't even built into the Atari sound chip.

Two additional programs,
"Sound Player" and "Sound Program Writer," let you play back the sounds you create with the Sound Editor or automatically generate stand-alone programs that can be converted into subroutines of your own BASIC programs.

## Developing Sounds

To get started, type in and save Program 1 below. The Sound Editor is the main program that lets you develop, modify, save, and load sounds.

When you type RUN, at first you'll see nothing but a black screen and hear a few beeps. The beeps signal that everything is running normally while the Sound Editor sets itself up. After a short delay, you'll see the Main Menu, which leads to several submenus for various functions:

## MAIN MENU

## 1-Develop sounds

2-Save/Load/Del/Dir sound envelopes 3-EXIT PROGRAM
Your choice (1-3): ?
Option 1 is the gateway into the main part of the program. Option 2 leads to the Input/Output Menu. Option 3 stops the program and exits to BASIC. Let's tackle option 1 first, since that's the meat of the Sound Editor.

When you press 1 , the Sound Menu pops up:
SOUND MENU
1-Envelope Editor, Voice 0
2-Envelope Editor, Voice 1
3-Envelope Editor, Voice 2
4-Envelope Editor, Voice 3
5-Play Voices Menu
6-Clear all voices
7-MAIN MENU
Your choice (1-7): ?

Options 6 and 7 are fairly obvious: 6 resets all four voices, discarding any existing values that may have been entered, and 7 returns to the Main Menu shown above. The other options let you design, modify, and play sounds in numerous ways.

Options 1-4 let you use a joystick to design individual sound envelopes for any of the four voices. Each Envelope Editor screen shows a graphic display of the current envelope and also indicates the pitch value assigned to that voice (see photos). Since envelopes aren't actually built into the Atari sound chip, but instead are handled by this program, let's backtrack for a moment and explain how they work.

## Attack And Retreat

One of the many characteristics which distinguish different sounds is the shape of their ADSR envelopes. ADSR stands for attack, decay, sustain, and release. These are the four stages of volume changes that occur during a sound's duration.

Attack is the initial rise in volume to the sound's peak volume. Decay is the decrease in volume that follows the peak. Sustain is the period in which the sound continues to be audible. And release is the final drop in volume to silence. Photo 1 is a typical ADSR envelope.

By changing the shape of this envelope, you can vary the effect of the sound. For instance, a percussive sound has an almost instantaneous attack, very short decay and
sustain, and a fairly sharp release (Photo 2).

If you pluck a guitar string and let it resonate, the attack is some-

Photo 1: An attack-decay-sustain-release envelope created with the Sound Editor.

Photo 2: A sharp attack and fast release is typical of percussion instruments.

Photo 3: Most musical instruments have a more gentle attack and release.

Photo 4: This envelope makes a backward sound.
what less steep and the sustain/release is much more gradual (Photo 3).

Since most real-world sounds have similar envelopes, sounds with a gradual attack and a rapid sustain/release often seem backward and artificial (Photo 4).

You can design almost any kind of ADSR envelope with the Sound Editor. At the bottom of the Envelope Editor screen for each voice is a joystick-controlled cursor. By pushing the joystick left or right, you can move the cursor horizontally to pick a position within the envelope. To set a volume level for that position, press the joystick button, then move the cursor up and down with the stick. When the cursor is at the desired level, press the joystick button again. The level is marked with a white block, and you can move the cursor left or right again to pick the next position.

If you change your mind and want to reset a volume level within the envelope, just move back to that position with the joystick and press the button as before. You can clear out the entire envelope by pressing C (Clear bars).

Other keyboard commands available on the Envelope Editor screens are L (Listen to the envelope), M (return to the Sound Menu), and S (change Sound). If you finish one voice's envelope and want to design an envelope for a different voice, press M for the Sound Menu, then select $1-4$ to switch to the other voice's Envelope Editor.

## Controlling Sounds

When you press S (change Sound) on an Envelope Editor screen, you get another screen that offers a wide range of control over the POKEY chip, which is responsible for Atari sound. Most of these controls are inaccessible from BASIC without PEEK and POKE. The control screen displays this information:

## Modify/Mix Sounds

PRESS TRIGGER TO LISTEN TO ALL

## VOICES

Switch clock from 64 KHz to 15 KHz
Hi-pass filter on ch.1, clock by 3
Hi-pass filter on ch.0, clock by 1
Join channels 3 and 2
Join channels 1 and 0
Clock channel 2 with 1.79 MHz

Clock channel 0 with 1.79 MHz
Change from 17 to 9 bit poly CHANNEL
VOLUME : 8
DISTORTION : 10
FREQUENCY :243
STATUS (0/1) :ON
-Press $X$ to Exit Back
to Editor-
Press the joystick trigger to play the voices; press it again to stop. The $X$ key returns you to the Envelope Editor.

The other features on the control screen let you change various POKEY settings for the voices. At the left and right of this screen, you'll notice a pair of pointers (greater-than and less-than signs). You can move the pointers up and down the screen with the $A$ and $Z$ keys, respectively. This is how you select a certain control you want to change.

The first eight controls (Switch clock from 64 KHz to 15 KHz through Change from 17 to 9 bit poly) can be set to either 0 or 1 . When the control is set to 0 , it is off; when it's set to 1 , it's on. For example, to switch on the control for Hi-pass filter on ch.0, clock by 1, you'd move the pointers to that line with the $A$ or $Z$ key, then type 1. To turn it off, you'd type 0 . You can turn any of the controls on or off in any combination.

The last five controls on this screen (CHANNEL through STATUS) work a little differently. After selecting one with the pointers, press the space bar. A question mark prompts you to enter a new value. Type in the new value and press RETURN. The allowable ranges are CHANNEL ( $0-3$ ), VOLUME ( $0-15$ ), DISTORTION ( $0-14$ ), FREQUENCY ( $0-255$ ), and STATUS $(0=\mathrm{ON}$ or $1=\mathrm{OFF})$. These correspond to the parameters in the BASIC SOUND statement, except for STATUS, which turns the current voice on or off so you can mix the different voices.

The first eight controls, however, aren't accessible with the SOUND statement; they POKE values into certain memory locations which directly control the POKEY chip. Perhaps the best way to learn what these controls do is to run the Sound Editor and simply experiment. For a more technical explanation, read the following section.

## Playing POKEY

The POKEY chip is accessed through nine memory locations known as AUDF1 (53760), AUDF2 (53762), AUDF3 (53764), AUDF4 (53766), AUDC1 (53761), AUDC2 (53763), AUDC3 (53765), AUDC4 (53767), and AUDCTL (53768). AUDCTL (AUDio ConTroL) controls both the four AUDio Frequency registers (which set the frequencies of the voices) and the four AUDio Control registers (which set the volumes and distortions of the voices). Each of the eight bits in AUDCTL (0-7) controls some aspect of the sound produced. These eight bits correspond to the eight controls in the Sound Editor:

5-Play Voices Menu
6-Clear all voices
7-MAIN MENU
Your choice (1-7): ?
After editing all four voices, you might want to hear what they sound like alone or in unison. Option 5 brings up the Play Voices Menu, which offers all 15 combinations of the four voices at a single keystroke:
PLAY VOICES MENU

- Voice Numbers -

# IBM Keyboard Customizer 

David Engebretsen

This tutorial for the IBM PC/PCjr explains how to customize your computer's keyboard with simple DOS 2.0 or higher commands. Besides reassigning key definitions to your own personal taste, you can create keyboard macros, define as many as 40 function keys and choose new screen modes and color combinations.

Have you ever wished you could change a key on the keyboard into another key, or make a single keystroke spell out an entire phrase? Would you like to move the colon and the semicolon keys, or put the Return key in a more convenient position? It is quite possible do to all this and more with a few simple commands from DOS. You can even create up to 40 different function keys which can be used to print a variety of command words or phrases of any length. With a little more work, you can even change your standard QWERTY keyboard into the efficient Dvorak format which can improve typing speed dramatically.

All this is made possible with the extended screen and keyboard control offered by DOS 2.0 and higher. Though the DOS manual devotes only one page to this subject, the process is not complicated. Let's look first at how to switch key assignments. Then we'll explore how to perform related tasks such as setting the screen mode, changing the background and foreground colors, and positioning the cursor.

## Boot Up With CONFIG.SYS

It is suprisingly easy to reassign any key or keys to a location that suits your own personal needs. The first step is to create a CONFIG.SYS file that installs an extended screen and keyboard control device driver when you boot the system. This can be done with the EDLIN system editor included on your DOS disk. From the DOS command prompt ( $>$ ) simply type EDLIN CONFIG.SYS and press Return. The drive will whir as it opens a new file; after a few moments your screen should look something like this:

## New file

Type the following lines, pressing Return at the end of each line: <br> \section*{$1 i$ <br> \section*{$1 i$ <br> DEVICE $=$ ANSI.SYS ${ }^{\circ}$}

Press Ctrl-Break, then type the number 3 and press Return. At this point you have created a configuration file that runs automatically whenever you boot the computer. The result is that the computer is then made ready to accept some new key assignments.

## Reassigning Key Definitions

The next step is to do the actual key switching. Since this can involve some odd character sequences, it's easiest to do this from within a BASIC program that stores the needed data in a text file on disk. Here is a program that demon-
strates the technique. We'll use it to create a file that changes the uppercase $Q$ to an uppercase D.

```
DN 1\emptyset A$=CHR$(27) + "[" + CHR$(3 \(4)+\) "Q" +CHR (34) + ";" + CHR \(\$(34)+\) "D" + CHR\$ \((34\) ) + " P "
FV \(2 \varnothing\) OPEN "KEY.TXT" FOR OUTPUT AS \#1
D0 36 PRINT \#1, A\$ 6n 46 CLISE \#1
```

Save this program as REASSIGN.BAS and run it. REASSIGN.BAS creates a text file that contains the following character sequence:
ESC ["Q"; "D" p
CHR\$(27) is the ASCII code for the ESC character; this is the control code which changes the uppercase Q into an uppercase D . To implement this change, insert the disk containing your new CONFIG.SYS file, then reboot by pressing Ctrl-Alt-Del simultaneously. This enables the ANSI device driver which in turn allows the keyboard to be redefined.

After answering the time and date prompts, type TYPE KEY.TXT at the DOS prompt and press Return. This action enters the special control characters into the computer's memory. Now whenever you type an uppercase $Q$, the system substitutes an uppercase D.

## Keyboard Macros

The same technique can be used to create a keyboard macro-a key that produces a multicharacter word or phrase with just one keystroke. To illustrate, let's redefine uppercase Q so that it prints the phrase The

Phrase whenever it's pressed. Reenter BASIC and load the REASSIGN.BAS program again, then replace line 10 as shown here:

```
EP 1\emptyset A$=CHR$(27)+"["+CHR$(34)+"
    Q"+CHR$(34)+";"+CHR$(34)+"
    The Phrase"+CHR$(34) +"p"
```

Now run the program again. This creates a text file that contains these characters:

## ESC ["Q";"The Phrase"p

Type SYSTEM to go back to DOS, then type the KEY.TXT file again. Now whenever you press $Q$ the computer prints The Phrase on the screen.

When creating the KEY.TXT file, it is also acceptable to substitute an ASCII code for the character. For example, say that you want to change uppercase Q back to uppercase D. Go back to BASIC again and change line 10 as shown here. Note that instead of $D$ we are using 68, the ASCII code for D:

Run the program, enter DOS, and TYPE the program. Uppercase Q should again produce a D .

## 40 Function Keys

Now let's create some extra function keys. By supplying an extended ASCII code, you can redefine the ten function keys alone or in conjunction with the Ctrl, Shift, or Alt keys. That comes to four sets of ten, or 40 keys. Rerun the example program after changing line 10 as shown here:

```
A6 1\emptyset A$=CHR$(27)+"[0;84;"+CHR$(
    34)+"DIR"+CHR$(34)+";13p"
```

The following text file is created: ESC [0;84;"DIR";p
The 0 before the 84 tells the computer to look for an extended key-code-a code that signals a special key combination. The extended keycode 84 represents Shift-F1. What we've done is redefine this key combination so that it prints DIR followed by a carriage return. Run the program, exit to DOS, and type KEY.TXT again. Hold down Shift and press F1: the disk directory is displayed.

Note the number 13 just before the $p$ in this character sequence. This is the ASCII code for Return. Adding this character to the end of
a character sequence has the same effect as pressing RETURN manually on the keyboard. The computer types the letters D-I-R, then issues a Return to carry out the command. You can find a complete list of all the extended keycodes on page G-7 of the IBM BASIC manual.

## Screen Modes And Colors

Using a similar method, you can also change the screen color or shift to a different screen resolution. To change colors, replace the lowercase $p$ in line 10 with a lowercase $m$, and supply an appropriate color number. For instance, change line 10 as shown here and create a new KEY.TXT file:

## EN $1 \varnothing$ A $=$ =CHRs (27) + " $[37$; 44m"

Now the program creates this text file:

## ESC [37;44m

When this file is TYPEd from DOS the screen turns blue.

The same procedure works for changing the screen mode. Change line 10 to this (note that an $h$ is substituted for the $m$ in the preceding example):
B6 $1 \emptyset \mathrm{~A} \$=\operatorname{CHR} \$(27)+"[=1 \mathrm{~h} "$
When you TYPE the resulting file from DOS, the screen goes into 40 $\times 25$ color text mode. To obtain $320 \times 200$ color graphics mode, simply change the number 1 in line 10 to a 4. Pages 13-9 and 13-10 in the DOS 2.0 manual contain a complete listing of all the numbers for different screen modes and color combinations,

The customizations you create using these techniques will stay in effect as long as you are working in DOS or a DOS-related program such as DEBUG or EDLIN. If you're tired of the normal white-on-black screen display, this simple technique can bring a welcome change. Note, however, that these changes disappear if you reboot the computer, go to BASIC, or run an application that imposes its own definitions on the system.

# Advanced Programming On The Atari ST 

Writing sophisticated programs on the Atari ST requires a more thorough understanding of the computer's operating system than was necessary on earlier machines. This article is an introduction to the various operating system routines available to ST programmers. It is an excerpt from COMPUTE!'s ST Programmers Guide (by the editors of COMPUTE! Publications.)

It seems quite natural to move the mouse pointer to an icon, click on it, and then double-click to open the window. Often you can choose options from menus at the top of the screen by simply pointing and clicking. Click on the menu bar and you can move the window around. You can resize it, expand it to fill the screen, or make the window go away, all with a few clicks of the mouse.

Making things simple for the user requires a wide variety of fairly complex routines for handling input, output, graphics, and so on. These routines are invisible to the user, who simply moves the mouse to point and click. But as a programmer, you may find it helpful to gain some acquaintance with the built-in TOS and GEM routines. The more you know about how they work, the more control you will have over the machine and the more power you can put into programs.

You can call many of these routines in BASIC with the GEMSYS or VDISYS commands, but to get the maximum speed and power from your ST, you'll need either a C compiler or a machine
language assembler.

## Alphabet Soup

We'll be referring to the various collections of routines by their initials: TOS, VDI, AES, and so on. We'll first look at what they are and what they do.

The Operating System (TOS) is either built into your ST computer in ROM or on a TOS boot disk. The most identifiable element of this operating system is the Graphics Environment Manager (GEM) desktop. However, the operation of TOS involves the interplay of many different, specialized components. The first step toward understanding GEM and TOS is to learn the name and function of each of the parts.

The desktop environment is actually a special type of GEM application, which exists only to perform file operations, including running other GEM applications. Every function that it performs, from examining disk directories to running other applications, can be duplicated by any GEM application using the facilities of the AES, VDI, and GEMDOS.

The GEM Virtual Device Interface (VDI) provides low-level graphics display and mouse input routines. This routine library includes primitive drawing operations like line, marker, circle, and polygon, as well as display management routines like clipping and block image copying.

The GEM Application Environment Services, AES for short, performs higher-level graphic and data management operations for maintaining the GEM desktop environ-
ment. Built on top of the GEMDOS file system and the GEM VDI, the AES routines make it much easier for programs to perform mouse and window operations.

The Disk Operating System GEMDOS performs characteroriented file and device input/output (I/O). Many of its routines are used by the GEM AES. GEM applications can also use GEMDOS for file access and for device operations. For the actual low-level operations, GEMDOS calls the Basic Input/Output System (BIOS), a group of routines which perform machine-specific tasks on the ST. The Atari XBIOS provides additional machine-specific operations. They are not used by GEMDOS, but are available to applications which need routines not available through GEMDOS or the GEM BIOS.

## AES In Detail

When you double-click on an application's icon, the desktop starts executing that application. Although you can move or resize an application's window, its output appears only in that window. An application can redraw its window when it is partially covered by an accessory without overwriting the accessory's window. When you click on the box at the upper left of an application's window, the application stops executing and the desktop returns.

All of these operations would be much harder to perform without the support of the AES, which is composed of a process dispatcher, a screen manager, a desk accessory buffer, and 11 subroutine libraries.

The process dispatcher allows one application and several accessories to wait for a user action simultaneously, a limited form of multitasking. When the system is booted, the accessory buffer is loaded with accessories. The process dispatcher suspends all accessories until a menu item for one of them is selected.

The procedures in the subroutine libraries support common operations on the application environment, the desktop. An application could perform most desktop operations without the AES, using the same VDI routines, but the standard AES routines make the job considerably less difficult. This is a powerful motivation for programmers to make user interfaces more alike, so the programs are easier to learn and use. Nonetheless, nonstandard interfaces can be built where needed, using either VDI or lower-level AES routines.

While the information presented here is not a thorough treatment of the AES, it is intended to be a concise overview of the whole library. It should give you some idea of how the AES is organized, what its constituent parts are and how they interact, and what facilities are available to the GEM programmer. More specific details about each routine's parameters and their values can be found in the Digital Research GEM literature and in sample GEM programs.

## Application Library

The application library is, in effect, the gateway to the rest of the AES. Its appl_init routine is used by an application to register with the AES and obtain a process ID. It also tells the AES to set up data structures to keep track of this application or accessory. When the program has finished, the appl_exit routine tells the AES to deallocate the ID number and data structures for this application.

When waiting for user input from the mouse or keyboard, a program can call one of the routines in the event library instead of waiting in a loop. Besides saving the programmer from writing a few more lines of code, a call to the event library freezes the application and allows possible multitasking, if an
event for another frozen process occurs first. Calls are available to wait for keyboard, mouse button, message, or timer events. Messages indicating that some action must be performed-like redrawing or moving a window-are usually awaited with an event library call. The routine most commonly used is evnt-multi, which allows an application to wait for more than one event at once.

The menu bar routine, in the menu library, is used to display or erase the menu bar. Another routine, menu register, is called by desk accessories to add a name to the Desk menu. Routines are also available to enable and disable menu items, to change the names of menu items, and to display a menu item in reverse video (as a selected item).

## Windows

The single most distinguishing feature of the GEM operating environment is the window. The output of applications and accessories running on the ST is displayed on the screen in separate windows, many of which can be moved or changed in size with the mouse. There can be as many as eight windows on the screen at once, and they can overlap in any way, but applications are advised not to use more than four of them if the Desk menu is displayed. Since desk accessories need to have windows available when they are activated, it's best to reserve four of the available windows for accessories. The routines in the window library perform services which are useful in the management of these windows.

The wind_create and wind_ delete routines are used to create windows and to dispose of them. When an application calls wind create to generate a new window, it establishes the maximum possible size of the window and the features with which the window is endowed, such as sliders, a name bar, a full screen box, and so forth. This routine returns a numeric identifier for the new window, called a handle. The wind_open call actually displays the window on the screen at a particular location. Conversely, a window can be hidden with the wind_close routine. The expanding
and shrinking box effects that are seen when many applications open and close windows are not part of the window library subroutines. Rather, they are independent effects routines from the graphics library, which an application can call for a little more flash.

Several window library routines provide information about windows. Wind_get can provide information about windows, including a window's position and size, and the positions of its vertical and horizontal sliders if it is so equipped. It can also return the handle of the top window on the screen (the window with the highest priority), as well as the set of rectangles that make up the visible portion of a window's work area, which can be a irregular shape if a window is partially covered by another. The wind_set routine is used to change the size and position of a window, the positions of its sliders or its name, or the set of controls attached to the window. It can also move one window to the top of the list of windows.

To determine which window the mouse currently points to, the wind_find routine can be called. Wind_calc doesn't operate on any particular window, but instead determines the work area size of a hypothetical window, given its external size and the set of controls it contains. It can also perform the reverse calculation, determining the external dimensions of a window.

The wind_update routine tells AES that an application is going to draw in a window or that an update is finished. When a window is being updated, no alerts, dialogs, or menus will be displayed in front of the window.

## Objects

Most items on the GEM desktop, including menus, alerts, and even windows, are organized as object trees. GEM objects include icons, strings, graphic boxes, and editable text fields. Trees-linked lists-of these objects can be managed with the routines in the object library. This library includes routines to add and delete objects from a tree, to compare the mouse's position to that of an object, to let the user edit a text object, and to draw the entire
tree on the screen. Object trees are usually stored in a file separate from the application that uses them. These resource files can be handled with the resource library, described below.

A form is a standard mechanism for getting information from the user. A form usually includes at least one modifiable object, like a text string or a button. In the case of a dialog, one type of form, the program needs to call the form dial routine to indicate that a dialog is beginning, and then draw the object tree which comprises the dialog, using the objc_draw routine from the object library. The form do routine should then be called to perform the interaction. Another call to form_dial restores the area of the screen where the dialog took place.

Two other forms, the alert and the error box, are more limited in their content and, accordingly, easier to implement. In the case of an alert, the AES builds an object tree containing the text string passed in the call to form_alert and handles all the details of display and interaction during that one call. The error box is even simpler. All that is needed is the number of a GEMDOS error code. An object tree containing the text which corresponds with that error will be displayed when form_error is called.

## Special-Purpose Libraries

The AES graphics library routines are lower-level interfaces to the display screen and mouse. The most commonly used routine in this library is graf_handle, which returns the handle-the identifier-for the currently opened VDI workstation. Every GEM application must call this routine at its start, after calling appl_init, since the handle is needed to open a new VDI virtual workstation to draw in. It is also necessary for calling VDI drawing routines.

To manage the mouse at a low level, the graf_mouse routine can be used to change the shape of the cursor. Graf_mkstate monitors the positions of the mouse, its buttons, and the keyboard, while grafwatchbox modifies the state of a box object depending on whether or not the mouse's pointer is inside
or outside the box.
Several common graphic effects are also available through the graphics library. Graf_rubberbox draws a rectangle between a fixed point and the mouse's position, changing the size of the box as the mouse moves. A moving box of fixed size attached to the mouse's position can be animated with graf_drawiox, while graf_movebox just moves a box between two positions without any consideration of the mouse. Graf_growbox and graf_shrinkbox are two animation routines which can be called when opening and closing windows, respectively, to show a box which moves and changes size.

The file selector library contains but one lonely routine, fsel input. This displays a standard dia$\log$ box, called a file selector, on the screen and allows the user to choose a filename from the directories of the various disks in the system. When the interaction is complete, it returns the pathname of the selected file to the calling application.

The objects that an application uses-its menus, dialogs, and so forth-can be stored separately from the application's code in a resource file. Resource files containing these objects are created with the GEM Resource Construction Set program. The resource library can then be used to load this file and to access its contents.

The rsrc_load routine searches for a resource file with a particular name and attempts to load it into memory. Rsrc_gaddr can be used by the application to find the address of a particular object or tree in the resource file that has been loaded. To allow applications to run with different screen resolutions in different display modes, all the sizes and positions of objects in a resource file can be expressed in characters instead of pixels. When the resource file is loaded, rsrc obfix must be called to convert the sizes into pixels in the current display mode. When a resource file is no longer needed, rsrc free deallocates the memory space that the resource occupies.

## Using GEMDOS

For many kinds of programs, the
windowed GEM environment might not be needed, so an alternative is available. A complete set of character-oriented I/O functions is provided in the GEMDOS library. Unlike many operating systems, GEMDOS is easily called from languages like C. Instead of taking parameters in the microprocessor's internal registers, which are not directly controllable in high-level languages, parameters are passed to these routines on the stack in the same way that parameters are passed between $C$ functions.

Even GEM applications need to call GEMDOS at least occasionally. For instance, the AES scrap facility expects applications to store and read the contents of the Clipboard directly from disk. Any program which handles some kind of document-a spreadsheet, word processor, database, and so onwill also need to call GEMDOS to load and store files.

To call GEMDOS, the 68000 microprocessor's TRAP \#1 instruction must be executed. The last word pushed on the stack gives the number of the routine requested. If the routine returns a value, it will be stored in the 68000's D0 register. Although this register cannot be directly read by a C program, C functions also return results in this register. A GEMDOS call can return a value in exactly the same manner as a call to another C function.

## Process Functions

00 Pterm0( ). Terminate with a return code of 0 .
49 Ptermres(size,code). Terminate, but keep the program's code in memory. A 32-bit parameter indicates how much memory should remain allocated. A 16-bit parameter gives the return code. This function is used by background programs, like print spoolers, to give up control of the foreground process.
75 Pexec(runflag, pathname,tail,environ). Load a program from disk. A one-word parameter indicates whether it should be run or not ( $00=$ run, $03=$ load only ). The second parameter is a pointer to the pathname of the file. Parameter 3 points to a command tail for the program, and parameter 4 is a pointer to its environment strings. If the file was loaded only, the result of the function is the load address. If it was executed, the result is its return code.
76 Pterm(code). Terminate, returning a one-word return code.

## Device I/O Functions

01 Cconin( ). Read a character from the console. No parameters are needed.
02 Cconout(char). Write a character to the console. A single, word-length parameter contains the character in its low byte.
03 Cauxin( ). Read a character from the auxiliary device.
04 Caux́out(char). Write a character to the auxiliary device.
05 Cprnout(char). Write a character to the printer.
06 Crawio(char). If the parameter is not $\$ 00 \mathrm{FF}$, write it as a character to the console; otherwise, return a character from the console with no echo, including control characters.
07 Crawcin( ). Read a character from the console with no echo and no control character trapping.
08 Cnecin( ). Read a character from the console with no echo, but trap ${ }^{\wedge} \mathrm{C},{ }^{\wedge} \mathrm{S}$, and ${ }^{\wedge} Q$.
09 Cconws(string). Write a zeroterminated string to the console. The long word parameter contains the address of the string.
10 Cconrs(buffer). Input a line of characters from the console, allowing line editing. The long word parameter contains the address of a buffer, the first byte of which holds the buffer's length. The second byte of the buffer will get the length of the string, and the string will be zero-terminated.
11 Cconis(). Check the status of the console input device. Returns -1 if a character is waiting, 0 if none is available.
16 Cconos(). Check the status of the console output device. Returns -1 if it is ready to receive a character, 0 if it is not ready.
17 Cprnos( ). Check the status of the print device.
18 Cauxis(). Check the status of the auxiliary input device.
19 Cauxos(). Check the status of the auxiliary output device.

## Time Functions

42 Tgetdate( ). Return the current system date. Bits $0-4$ of the result contain the date, $5-8$ contain the month, $9-15$ contain the year minus 1980 (up to 2099).
43 Tsetdate(date). Set the current system date to the word value in the parameter.
44 Tgettime( ). Return the current system time. Bits $0-4$ contain seconds $/ 2,5-10$ contain minutes, $11-15$ contain hours.
45 Tsettime(time). Set the current system time to the word value in the parameter.

## System Functions

32 Super(). Enter 68000 supervisor mode.
48 Sversion( ). Return the GEM version number.

## Drive Functions

14 Dsetdrv(drive). Set the default disk drive to the value passed as a parameter. Values $0-15$ indicate drives A-P.
25 Dgetdrv( ). Return the value of the current default drive.
54 Dfree(buffer,drive). Ask for information about a disk. The first parameter contains the address of buffer to receive the information. The second parameter is a 16 -bit value indicating the drive being queried. The buffer gets four values: free space, number of clusters on drive, size of sector in bytes, size of cluster in sectors.
57 Dcreate(pathname). Create a subdirectory. The long word parameter contains the address of null-terminated string for the pathname of the new directory. If the result is nonzero, the operation failed.
58 Ddelete(pathname). Delete a subdirectory.
59 Dsetpath(pathname). Set the current default pathname to the string addressed by the parameter.
71 Dgetpath(buffer, drive). Store the current directory for a drive in a 64byte buffer addressed by the first parameter. The second parameter indicates which drive $(00=$ default drive, $01-10=\mathrm{A}-\mathrm{P}$ ).

## File Functions

26 Fsetdta(DTAbuffer). Use the long word parameter to set the address for a 44-byte file data buffer. This buffer is used only when searching for a file (routines 78 and 79).
47 Fgetdta( ). Return the address of the file data buffer.
60 Fcreate(pathname,attributes). Create a file named by the string addressed by the first parameter. An additional 16 -bit parameter indicates the file's attributes $(01=\mathrm{RO}, 02=$ hidden $)$. The result is a 16 -bit file handle.
61 Fopen(pathname,access). Open the file named by the string addressed by the first parameter. An additional 16-bit parameter indicates type of access $(00=$ read only, $01=$ write only, $02=$ read and write). The handle of the file is returned as the function's result.
62 Fclose(handle). Close a file. The handle of the file is passed as a parameter.
63 Fread(handle,count,buffer). Read from a file. The first parameter is the handle of an open file and the second is a four-byte count for the transfer. The third parameter is the address of a buffer to which the bytes are to be read. The result returned by the function is the number of bytes.
64 Fwrite(handle,count,buffer). Write to a file. The function uses the same parameters as Fread.
65 Fdelete(pathname). Delete the file named by the string pointed to by the parameter.
seek(count,handle,operation).
Move the file pointer. The first parameter is a signed long word representing a byte count. The second parameter is a file handle. The third indicates the meaning of the byte count ( $00=$ absolute position $N$ bytes after the start of file, $01=N$ bytes forward or backward from current position, $02=N$ bytes before the end of the file). As a result, it returns the absolute file pointer position.
67 Fattrib(pathname,operation,attributes). Read or change the attributes of file. The first parameter is a pointer to a pathname for the file. The second parameter is 00 for get, 01 for set. The third parameter is a word containing the attributes.
69 Fdup(handle). Return a copy of the file handle passed as a parameter.
70 Fforce(handle1,handle2). Force the first parameter, a file handle, to point to same device as the second parameter, also a handle.
78 Fsfirst(pathname,attributes). Search for the first file which matches the search string addressed by parameter 1. The string can contain the * and ? wildcards. Parameter 2 contains the attribute flags of the file. The 44 -byte file data buffer set by Fsetdta holds size of file in bytes 26-29, and the file's name and type in bytes 30-43.
79 Fsnext(). Search for another match to the file, using the data buffer at DTA. This function takes no parameters.
86 Frename( 0 ,oldname, newname). Rename a file. Parameter 1 is a word with the value 0 ; parameter 2 is a pointer to the old pathname of the file; parameter 3 points to the new pathname.
87 Fdatime(buffer,handle,operation). Get or set a file's date and time information. Parameter 1 is a pointer to a two-word buffer-a time word and a date word. Parameter 2 is a file handle, and parameter 3 is a word which indicates which operation to perform ( $00=$ set, $01=$ get $)$.

## Memory Functions

72 Malloc(count). Allocate some number of bytes to the calling application. The length of the block requested is passed in the parameter, a long word. It returns a value of 0 if the request fails, or the address of the block allocated if it succeeds. If the parameter has a value of -1 , the number of free bytes is returned instead.
73 Mfree(address). Free a block of memory. The four-byte parameter should contain the address of the block.
74 Mshrink(0,address,length). Reduce the size of an allocated block of memory. The first parameter must be a word with value 0 , the second parameter is the address of the block, and the third parameter is the number of bytes which should remain in the block.

# Block PEEK And POKE For Atari 

Ronald R. Lambert

Here is a convenient way to eliminate long initialization delays caused by POKEing large amounts of data into memory. It works entirely in BASIC and works very fast. The demonstration program moves the entire character set in an instant and redefines the keyboard as a Dvorak layout. This technique can be used on all Atari 400/800, XL, and XE computers and is recommended for intermediate to advanced BASIC programmers.

PEEK and POKE are among the fastest commands in BASIC. But because they handle only one byte at a time, it can take a while to transfer large blocks of data from one area of memory to another. We've all waited while programs with long loops PEEK a series of memory locations, or READ numbers from DATA statements, and then POKE the numbers into memory somewhere else. Perhaps the program is redefining the character set, or setting up player/missile graphics, or building a machine language subroutine, or creating a new keyboard definition table. Whatever's happening, it slows things down.

Lengthy FOR-NEXT loops with PEEK and POKE or READ and POKE are the primary cause for tedious delays while these programs initialize. No one likes to sit staring at a blank screen for very long. The program usually prints a
message like "Please wait while I initialize," but isn't there a better way? Sometimes a machine language subroutine can help speed things up, but if you can't write in ML yourself, finding a routine exactly suited to the needs of your program can be difficult.

Fortunately, Atari BASIC's flexibility provides a solution. It's possible to transfer large blocks of data from Read Only Memory (ROM) or program lines to any area of Random Access Memory (RAM) virtually instantaneously-with BASIC commands only. The secret is called the string offset technique. By modifying the variable value table (a section of memory which keeps track of BASIC program variables), you can redefine any string and relocate it anywhere in memory.

Here's a quick overview of how the technique works. Suppose you set up a string called ROM\$ which contains a block of data found in ROM-the character set data, for instance. Next, you set up another string called RAM\$ in the area of RAM to which you want to move the data contained in ROM\$. To copy the data from ROM to RAM, then, all that's required is the simple statement RAM $=$ ROM $\$$. Is that easy enough? Using the string offset technique, any portion of ROM-or all of ROM, if you make the strings big enough-can be copied into RAM in the blink of an eye.

## The Variable Value Table

To use the string offset technique, you have to learn how to modify the variable value table and the string offset pointers. This isn't too difficult if you tackle the job one step at a time.

The first step is to make things easier for ourselves by insuring that ROM\$ and RAM\$ are the first variables found in the table. We can do this by making ROM\$ and RAM\$ the very first variables defined in the program. Enter NEW as a direct command before typing the first program line containing these names. Then dimension the variables in this order:

## 10 DIM ROM\$(length),RAM\$(length)

where length is the length of each string in characters as required by your program. If you're moving character set data, for instance, you'd dimension these strings to the number of bytes in the character set-1024 bytes in graphics mode 0 or 512 bytes in modes 1 and 2. (Usually you'll dimension ROM\$ and RAM\$ to the same length if you're transferring a block of memory.)

However, if you are using an Atari 400 or 800 with the old BASIC revision A, a major caveat applies. You cannot move blocks of memory that are exact multiples of 256 bytes. Attempting to move blocks of this size will trigger the infamous BASIC lockup bug, freezing your
computer until you turn the power off and back on-which will, of course, result in the loss of your program. [For more information on the lockup bug, see this month's "Readers' Feedback" column.-Ed] You can determine your version of BASIC by entering PRINT PEEK (43234). If the value returned is 162 , you have revision A. If 96 is returned, you have revision B (built into most 600 XL and 800 XL models), and 234 indicates revision C, available on cartridge from Atari and built into the XE models.

The string offset technique will work as described with revision A as long as you make sure your block length is not an exact multiple of 256. So for this example you should substitute 1025 instead of 1024. This will transfer an extra byte of memory following the character set, but that doesn't cause any problems and it prevents the lockup bug from biting.

The second step is to make BASIC think that ROM $\$$ is actually 1024 bytes long (remember, use 1025 for revision A BASIC). The DIM statement reserves memory for the string but doesn't actually define the string. Use a line like this:
$20 \operatorname{ROMS}($ length $)=" ;$
By defining the last character in the string as a space, BASIC is forced to treat ROM $\$$ as a 1024 -characterlong string, even though no other characters have been defined.

The third step is to calculate the location of the variable value table in memory, with a statement like this:

## 30 VT $=$ PEEK(134) + PEEK(135)*256

The variable VT equals the starting location of the variable value table. Each string which is declared in an Atari BASIC program has eight bytes in this table. We'll see the significance of these bytes in a moment.

After these variables are set up, the first eight bytes in the variable value table (VT to VT+7) contain information for ROM\$, and the next eight bytes (VT+8 to VT+15) contain information for RAM\$.

## Locating The Strings

To use the string offset technique, we're primarily interested in the
third and fourth bytes for each of these two variables in the variable value table. The memory locations for these bytes can be expressed as $\mathrm{VT}+2$ and VT +3 for ROM\$, and $\mathrm{VT}+10$ and VT +11 for RAM\$.

What do these bytes signify? Briefly, each pair of bytes is a low-byte/high-byte combination that indicates the relative displacement of each string from the starting location of the first string in the program. Since we've made sure that the first string in the program is ROM\$, the values stored in VT+2 and VT +3 for ROM\$ will both be zero. And since we've also made sure that RAM\$ is the second string in the program, the values stored in VT +10 and VT +11 for RAM\$ depend on the length of ROM\$.

For instance, if ROM\$ is dimensioned to 1024 , then the memory which BASIC sets aside for RAM\$ must begin 1024 bytes after the start of ROM\$ to leave room for ROM\$. Therefore, the value stored in VT +10 is zero, and the value stored in VT +11 is four. (Since VT +11 is the high byte of the offset, it's multiplied by 256 , which equals 1024.)

Actually, the memory for ROM\$ and RAM\$ does not begin at these locations. Instead, you have to add another value indicated by the string offset pointers at memory locations 140 and 141. If you use this statement:

## 40 SF $=$ PEEK(140) + PEEK(141)*256

then the variable SF returns the number that should be added to the relative displacement values given in the variable value table. (Since the relative displacement of the first string is zero, this means that SF always equals the address of the first string.)

The reason for this seemingly complicated arrangement, incidentally, is that the computer can now easily relocate strings as the program length changes simply by altering the offset pointers.

## Setting The Table

Now it's clear how the string offset technique works: We can relocate a string anywhere in memory by merely POKEing different values into its relative displacement indicators in the variable value table.

For example, suppose we want
to move ROM\$ to the starting memory address of the standard character set in ROM, which is location 57344 . We subtract the amount of the string offset (SF) from 57344, and convert the remainder into low-byte/high-byte numbers. Then all we have to do is POKE LS into VT +2 and POKE HS into VT +3 , and ROM $\$$ is moved to the proper location. The statements might look like this:

## $50 \mathrm{~S}=57344-\mathrm{SF}: \mathrm{HS}=\mathrm{INT}(\mathrm{S} / 256)$ : <br> LS $=\mathbf{S}-\mathrm{HS}^{*} 256$

60 POKE VT +2 ,LS:POKE VT +3 ,HS
Now we can turn our attention to RAM\$.

The usual place to set up a new character set is below RAMTOPthe memory location returned by $\operatorname{PEEK}(106)^{*} 256$. Some people prefer to move RAMTOP down by POKEing a lower number into register 106, issue a new GRAPHICS command to set up a new display list and screen memory below the altered RAMTOP, and then put the new character set above the new RAMTOP. There are advantages and disadvantages to each method, including a "RAMTOP dragon" to watch out for. We'll stick to the easiest method for this example. Let's simply put the new character set eight pages (2048 bytes) below RAMTOP. This leaves enough room for the 1024-byte character set, plus another 1024 bytes for the display list and screen memory in graphics mode 0 .

We move RAM\$ to this location by figuring the proper values and POKEing them into $\mathrm{VT}+10$ and VT+11:

## 70 RAMPAGE $=$ PEEK(106)-8

80 S = RAMPAGE* 256 -SF:HS $=$ INT
(S/256):LS $=\mathbf{S}-\mathrm{HS}^{*} 256$
90 POKE VT +10 ,LS:POKE VT +11 , HS
Finally, all that remains is one simple step:
100 RAM $\$=$ ROM $\$$
Instantly, the character set in ROM is copied into RAM, where it can be customized to suit our purposes.

## Two Potential Problems

There are two things to watch out for when using the string offset technique. First, if you set up a string in a section of RAM where vital tables or pointers are stored,
then do anything to change the contents of the string, or press BREAK and enter a direct command (which causes BASIC to shift strings and all their contents in memory), the computer may behave very strangely. You'll probably have to turn the machine off and on again to regain control.

Second, you cannot POKE a negative number into the variable value table without getting an error message. How, then, can you move a string to a location in memory lower than the value (SF) indicated by the offset pointers? Simple. POKE the offset pointers to zero, and POKE memory locations 140 and 141 to zero. (Make sure you do this before relocating any strings, or they'll all be moved again when you change the offset pointers.) But don't leave zeros in locations 140 and 141. Save the original values and POKE them back in when you're finished transferring the data.

## A Dvorak Demo

The program following this article demonstrates the string offset technique and accomplishes several things. First, it copies the standard character set from ROM into RAM (eight pages below RAMTOP) and modifies it so that the CTRL key characters can be recognized more easily. If you press CTRL-A, for example, you won't get the usual graphics symbol; you'll get an underlined A, so you can see at a
glance which keys to press to type that character. This way, you can enter ATASCII (Atari ASCII) characters directly into memory from statements in program lines without using DATA statements and slow, one-byte-at-a-time POKEs, because all the characters are immediately recognizable. This character set modification is accomplished in an eye-blink.

Second, the program copies the keyboard definition table from ROM and loads it into memory page 6, a normally unused portion of RAM from locations 1536-1791. Then the program modifies the keyboard table to create a Dvorak keyboard layout. Designed by August Dvorak after 20 years of scientific study and testing, the Dvorak keyboard makes things as easy as possible for typists, in contrast to the conventional QWERTY keyboard, which doesn't put the most frequently used keys on the home row. Many typists are able to convert from QWERTY to Dvorak touch-typing within a few days, and often find they can type faster with substantially fewer errors.

The Dvorak keyboard portion of the program will not work with the older 400 and 800 models because it relies on the KEYDEF pointer at locations 121-122. This pointer was added to the improved operating system in the XL and XE models, and is not implemented in the original Atari operating system

ROMs. Owners of 400 s and 800 s can still use the redefined character set portion of the example by simply omitting all lines numbered higher than 215. If you are using revision A BASIC, you'll also need to change the 1024 s in lines 10 and 20 to 1025 s .

Notice that this program must deal with the problem mentioned above: The memory address 1536 is lower than the value for SF , so the string offset pointers at locations 140 and 141 have to be changed.

A FOR-NEXT loop is used to enter ATASCII characters 0 through 26 , so this part of the program takes a little longer-almost a whole second. You could make it run even faster by typing the CTRL key characters directly in string assignment statements, as seen in lines 140 to 170 . This is where the new character set could come in handy.

As a final bonus, the program demonstrates a customized keyboard entry routine that works faster than the GET function. It does this by reading a hardware location (53769), then using the keyboard conversion table located in ROM (64337 to 64592) to translate the keyboard codes into ATASCII codes the same way the operating system does.

When the program runs, it lets you toggle back and forth from QWERTY to Dvorak, just like on an Apple IIc. Press SHIFT-ESC to

## Atari Dvorak Keyboard Layout

toggle．If you become a real Dvorak fan，you can even find keycap stick－ ers at many office supply stores to modify your keyboard．The accom－ panying figure shows the Dvorak layout．

## Additional Notes

A few modifications to the standard Dvorak layout were necessary be－ cause of the special functions and extra keys on the Atari keyboard． The seldom－used brackets may be typed with CTRL－9 or CTRL－0．The $+=$ key，normally located at the upper right of the Dvorak key－ board，has been moved down．The ＊\ key has been retained in its standard Atari position because these characters have extra use as arithmetic functions in program－ ming．Since the Atari has no cent symbol，this has been replaced with the vertical line as uppercase 6 ．In place of the asterisk（uppercase 8 on the Dvorak keyboard）is the back－ slash．The＇＂key has been ex－ changed with the $;:$ key to avoid conflict between the CTRL－up ar－ row and CTRL－semicolon．

The Atari logo key is the in－ verse video key on the Atari 400／ 800 ，and it is reversed with the right SHIFT key on those models．Re－ grettably，the Atari has no dash in its character set．While the useless underline could be redefined as a dash for screen display，most Atari printers also lack the dash．

If you enter NEW or load a new program after this one is run， the new character set with readable CTRL key characters remains active （as long as the new character set is not overwritten）．Press SYSTEM RESET or POKE 756，224 to restore the old character set．The following POKEs switch on the Dvorak key－ board even after a NEW command： POKE 121，0：POKE 122，6．To switch back to QWERTY，use POKE 121，81：POKE 122，251．

The next time you need to transfer large blocks of data from one portion of memory to another， try using the string offset technique． It gives you the best of both worlds： the convenience of BASIC and near－machine language speed． Never again will you have to sit staring at a blank screen waiting for your programs to move large amounts of data in memory．

# Screen Machine II: A Sketchpad With Pull-Down Menus For PC and PCjir Part 1 

Charles Brannon, Program Editor

Pull-down menus in IBM BASIC? It's no fantasy-presented here is a fullfeatured drawing program that illustrates the convenience and flexibility of a menu-driven user interface. Next month, in Part 2, we'll show how you can add these menu routines to your own programs. This month's drawing program, "Screen Machine II," runs on any IBM PC or compatible with a color/graphics adapter and BASICA, or a PCjr with Cartridge BASIC. Joystick or touch tablet optional.

Software features first popularized by the Apple Macintosh are finding wider acceptance throughout the computer industry. Pull-down menus and point-and-click selections have become a way of life among owners of the Macintosh, Commodore Amiga, and Atari ST. With the advent of operating system veneers such as Microsoft Windows, GEM, and Topview for IBM machines, even more people are getting excited about mousing around on their computer.

Without the software tools to implement these techniques, though, programmers have to laboriously write all the routines needed for pull-down menus, icon selection, and windowing, taking time away from programming the application itself. Tools such as Windows and GEM do the trick for advanced programmers, but BASIC programmers have to reinvent the wheel if they want to add these useful features.

You might think BASIC is not fast enough to emulate the features of operating systems written in turbocharged 8088 or 68000 machine language, but it's almost always possible to tease just a little more power out of BASIC. Although a complete mouse-based user interface is a bit much to expect, I've developed a set of generalized subroutines that any BASIC programmer can use to support fancy pulldown menus in Microsoft Advanced BASIC (BASICA) or PCjr Cartridge BASIC. The routines require bit-mapped graphics, so you need a color/graphics adapter if you're using a PC or compatible. (The PCjr has a built-in color/gra-
phics adapter.) By changing only a few small subroutines, the package can be adapted for other graphics cards and pointing devices.

Rather than illustrate these routines with a plain-vanilla demo program, I though I'd provide a more convincing illustration: a fullfeatured drawing sketchpad. "Screen Machine II" is a descendant of the original "Screen Machine," a drawing program published about two years ago in COMPUTE!'s PC \& PCjr Magazine.

The original Screen Machine used a traditional command-driven user interface. Individual keystrokes were required to activate special commands. For example, to draw a line, you first pressed the space bar to "nail down" one endpoint, marking the spot with a cross. You then moved the cursor to a new position and then pressed L to connect the marked spot with the new cursor position. A line was drawn to connect the points. To draw a circle, you first set your mark to represent the center of the circle, then moved the cursor to a point along the desired circumference. You had to visualize the circle
in your mind, because it wasn't actually drawn until you pressed C.

Although Screen Machine had plenty of features (and in the hands of a talented artist was capable of making beautiful pictures), the stumbling block was the indirect method of using the program. You had to memorize every command or frequently refer to a list of commands. This approach works well once you've mastered a program, but it can alienate the newcomer or occasional user. In a drawing program, especially, it's crucial not to break the flow of ideas between the artist and the canvas.

## Screen Machine II

Thanks to pull-down menus, you don't have to memorize a lot of commands to have fun with Screen Machine II. All of the functions are available for selection whenever you need them.

The listing following this article is the minimum required to publish Screen Machine II as a ready-to-run program. Screen Machine II needs almost all of BASIC's 64 K memory space, so the original program listing with full comments didn't leave enough memory to run. Next month, however, we'll present a fully REMarked version that shows exactly how the program works, along with a tutorial on using the menu routines in your own programs.

When you first run Screen Machine II, there is a short delay, then the drawing screen appears. The top line of the screen shows which menus are available: Picture, Tools, and Preferences. Your color palette appears at the bottom of the screen, initially showing boxes filled with cyan, magenta, and white paint.

A pointer cursor appears near the middle of the screen. You use this pointer to select items from menus, dip into the paint to change your drawing color, or to draw figures. The pointer can be controlled with a joystick, a touch tablet such as the KoalaPad, or the cursor keys (make sure Num Lock is in the correct position for cursor control). When using the joystick, you may want to unlock it for free-floating movement.

If you don't have a joystick or touch tablet, you can disable the
joystick routine in Screen Machine II to prevent interference with the cursor controls. Change line 340 from FROZEN $=0$ to FROZEN $=-1$.

To use a light pen or mouse controller, you need to modify the subroutine at line 20000, which we'll discuss next month. The use of menus, though, is not tied to the actual pointing device used, such as a mouse.

## Calibrate Your Joystick

The pointer responds most naturally with a touch tablet, so the program is initially set up to use a KoalaPad. The KoalaPad simulates the joystick, but has a greater range, so if you use a joystick with Screen Machine II you'll only be able to position the pointer within the up-per-left quadrant of the screen. You may also have problems using a different touch tablet, since not all tablets return the same values. When you first run the program, then, you need to calibrate your joystick or tablet. The calibration option is available under the Preferences menu, but we haven't discussed how to use the menus yet. And until you calibrate your joystick, you probably can't access the menu item that is used to select the calibrate option. Fortunately, you can also press the J key-a keyboard shortcut-to activate the calibration feature.

After you press J, you're first asked to move the joystick to the upper-left corner, then press the button. (Screen Machine II only uses the top button on the joystick, or the left button of the touch tablet.) This first action sets the origin of your pointing device. If you're using a touch tablet, it is vital that at this point you merely lift the pen off the tablet surface and press the button. This lets Screen Machine II know when you are pressing down on the tablet, and when you lift the pen off the tablet. The value for "pen up" is the same as the coordinates for the upper-left position of the tablet, so it's best just to press the button without touching the tablet surface, in order to make sure that Calibrate sees the right value. With a joystick, move the stick to the northwest corner before you press the button.

Next, you're asked to move the
joystick to the lower-right corner, then press the button. With the touch tablet, move the stylus or your fingertip to the southeast corner of the tablet, and while pressing firmly with the stylus, click the button. It may be best to use a position slightly above and to the left of the lower-right position, since if you put the pen off the tablet surface, no value is generated.

In general, you must press very firmly against the tablet surface, almost to the point of scoring the tablet, in order to avoid false readings caused by intermittent stylus contact. These false readings aren't caused by Screen Machine II, but by the tablet. A special routine could be used to compute the average position of the touch tablet within the last second, then reject values far out of range, but this would slow down the program to a crawl. As it turns out, this jitter is rarely a problem, since the BASIC program samples the touch-tablet too slowly to see many of the transient glitches.

After calibration, you should be able to move the pointer freely as you slide your finger or stylus across the tablet surface, or by moving the joystick. Control may seem clumsy at first, especially with the joystick, but improves considerably with practice. If you get no response at all, check the joystick or tablet cabling, and press J to calibrate again.

## Keyboard Confrol

If you don't have a joystick or touch tablet, you can use the keyboard cursor controls to move the pointer arrow. The keyboard isn't the fastest way to scurry across the screen, but it is exact. The joystick, however, overrides keyboard control (although you can use a properly calibrated touch tablet along with the keyboard), so you need to press the K key right away to freeze the joystick and enable keyboard control. The K key alternately freezes and reenables the joystick, and is a keyboard shortcut for the Keyboard command on the Preferences menu.

There are two ways to use the keyboard controls. The pointer can move one pixel at a time for fine movements, but it could take all day to inch your way across the
screen. If you press a cursor key rapidly or hold it down as it repeats, the cursor accelerates. It first moves one pixel at a time, then two, then three, until it's moving at the top speed of 12 pixels per keypress. If you stop pressing the cursor key, press another key, or release the key for a moment, the acceleration reverts to one pixel per keypress. If you want fine control, press and release the cursor key slowly, allowing time between each keystroke to prevent acceleration.

## Keyboard Shoricuts

| Key | Menu |
| :---: | :--- |
| U | Picture/Undo |
| N | Picture/New |
| O | Picture/Open |
| S | Picture/Save |
| Q | Picture/Quit |
| D | Tools/Draw |
| L | Tools/Line |
| R | Tools/Rectangle |
| C | Tools/Circle |
| A | Tools/Airbrush |
| P | Tools/Paint |
| B | Preferences/Bkgd color |
| K | Preferences/Keyboard |
| J | Preferences/Calibrate |

Unfortunately, the program is not fast enough to keep up with the full repeat rate of the cursor keys, so even after you release the key, the program is acting on up to 15 pending keystrokes. It's best to control the number of keystrokes yourself by just pressing the same key rapidly rather than holding it down to repeat. If you do hold down the key, release it before the cursor reaches its destination. It will keep going for a short distance, then stop. With practice, you can time things right so that the cursor ends up exactly where you anticipated.

## Using The Menus

To access a menu, just move the arrow cursor so that it points at one of the menu titles: Picture, Tools, or Preferences. The tip of the arrow is the active point, so make sure it is within the menu bar and touching the desired menu title. Now press and release the button. (The keyboard equivalent for the button is the INS key, conveniently located beneath your thumb when you use the cursor keypad.) The menu title reverses color, and the menu drops down.

Note that this differs from the
way menus are selected on other machines. On the Atari ST, menus drop down automatically if you merely point at a menu title. On the Macintosh and Amiga, you point at the menu and click to pull it down. You have to continue to hold down the button to keep the menu displayed, and move the pointer within the menu to select an item. To actually make the choice on a Mac or Amiga, you release the mouse button.

In contrast, with Screen Machine II you press and release the button to drop down the menu, move the pointer to the item you want, then press the button again to select the item and remove the menu. This technique is most appropriate when you're using pointing devices such as a joystick or cursor keys, because it's difficult to hold down a button while moving the pointer.

For example, if you point to Picture, then click the button, it drops down a list containing the choices Undo, New, Open, Save, View, and Quit (see figure 3). To the right of each selection are the keyboard equivalents: $\mathrm{U},{ }^{\wedge} \mathrm{N}, \mathrm{O}, \mathrm{S}, \mathrm{V}$, and ${ }^{\wedge} \mathrm{Q}$. Instead of pulling down a menu and selecting a choice, you can just press the appropriate keyboard shortcut. The ${ }^{\wedge}$ character indicates that you should press the CTRL key along with the following character: " N means that you should press N while holding down CTRL.

Using the more cumbersome CTRL-N and CTRL-Q sequences, instead of merely $N$ or $Q$, helps prevent you from casually erasing the screen or exiting the program. Since these are destructive options, the CTRL key is used to guard against accidental keypresses. Use the accompanying table as a quick reference to keyboard shortcuts.

## Selecting A Menu Item

To select a menu item, point the cursor at the desired item. As you slide the cursor up or down within a menu, the item you point to is highlighted in reverse video. You then press and release the button to select the highlighted item. To cancel a menu selection, either move the pointer outside of the menu, or move it to point at the menu title so
that no other items are selected when you press the button. If you move the cursor to the left or right of the menu border, the menu is automatically canceled. You'll hear an "uh-oh" sound effect to confirm that you've canceled the menu.

When you select an item, on the other hand, it flashes twice, emitting little tweeting sounds to let you know that you've chosen a valid option. (By the way, if you don't want any sound effects, change line 320 to read SNDFX $=0$.) After you select a menu item, some action is usually performed. If you select New from the Picture menu, for instance, the screen clears. Use Quit to exit the program. Following is a quick tour of the menus-we'll discuss the meaning of each item later on.

Some menu items select a setting for the program. The Tools menu contains the choices Draw, Line, Rectangle, Circle, Airbrush, and Paint. This menu is used to select the current drawing tool. Only one tool is active at any time. When you click the button while pointing at the drawing surface, rather than at the menu bar or within the palette, the current tool is activated, and you start the drawing action. In Draw mode, you can draw connected lines as you move the pointer about. In Line mode, though, you stretch a "rubber-band" line across the screen, emanating from the point you first clicked on. When you press the button a second time, the rubber-band line disappears, and the desired line is stamped down. In Paint mode, each click initiates a flood-fill, used to color enclosed figures.

The Tools menu indicates the current tool by placing a check mark next to it. A check mark can show which of several items is currently selected. If you select another drawing tool, the check mark moves to the new tool. In the Tools menu, a selection mutually excludes all other selections.

On the other hand, a check mark can also be used to show the status of several on/off settings. The Preferences menu lets you select $320 \times 200,640 \times 200$, and 320 $\times 200 \mathrm{PCjr}$ drawing modes; two color palettes for the $320 \times 200$ graphics mode: cyn/mag/wht and
red/grn/yel; as well as Bkgd color (background color), Keyboard mode, and Calibrate. More than one item can be checked in the Preferences menu. You obviously can't draw both in both $320 \times 200$ mode and $640 \times 200$ mode at the same time, so only one of the three graphics modes is checked. However, while in $320 \times 200$ mode, you can choose either of the two color palettes, so both $320 \times 200$ would be checked as well as either cyn/ mag/wht or red/grn/yel.

## Ghosted Items

If you select $640 \times 200$ mode, some menu items under Preferences are no longer appropriate. It isn't possible to switch color palettes or change the background color while in $640 \times 200$ mode, so the inappropriate menu selections need to be disabled. Also, the $320 \times 200 \mathrm{PCjr}$ mode, which permits 16 colors, only works with the PCjr, so this selection should be made inaccessible when running on a PC.

## Figure 1: Ghosted liems

In $640 \times 200$ mode, the menu items cyn $/ \mathrm{mag} / \mathrm{wht}$, red/grn/yel, and Bkgd color are disabled, and the text of the menu items is distorted to show that you can't access them (see Figure 1). This distortion dims and garbles the text-such a menu item is ghosted out, as if the text was a "ghost" of the original text. The $320 \times 200$ PCjr option is ghosted out when running on the PC. A ghosted menu item can't be selected; you can't even highlight it by pointing to it.

A ghosted item immediately
tells you that the menu item is inappropriate for the current environment. If you wonder which commands work in which modes, ghosting makes it obvious. Along with ghosting and the check mark, a menu can be documentation, online help, and a status report, as well as the device used to change these settings or activate commands.

## Drawing Tools

The pointer arrow is the pass key to all the functions of Screen Machine II. You use it to select a menu item, sketch on the drawing surface, or choose a new drawing color. You already know how to use the menus. To change drawing colors, just point within the box containing the desired color and click the button. A border encloses the current drawing color so you can tell at a glance which color is being used. In $640 \times 200$ mode, you can only switch between black and white, of course. On the PCjr, you can select the 16 -color drawing mode (see below).

## Figure 2: The Tools Menu

Your default drawing tool is Draw, as you can confirm by looking within the Tools menu. With all the tools, you start the drawing action by clicking the button while pointing at the drawing area. The drawing area is bordered by the menu bar, the color palette, and is enclosed within a rectangle. You can't draw anywhere outside of this border.

In Draw mode, the first button click initiates the mode. The cursor disappears (to speed up drawing), and a point is plotted at the cursor position. You can now move around on the screen, leaving a trail behind, as you sketch freehand with the joystick, tablet, or cursor keys. The cursor keys are especially useful for touch-up work or small, complex figures. Again, you can use the Keyboard option from Prefer-
ences if you need to disable the joystick. If you press the button (or merely lift the stylus from the tablet surface), you exit drawing mode, and you can once again freely move the cursor without drawing on your screen canvas.

In Line, Rectangle, and Circle modes, the first click sets the first coordinate for the figure. You then move the pointer about to change the size or position of the figure, then press the button again to finalize the figure. While previewing the figure, the line, circle, or rectangle is repeatedly drawn and erased to allow movement. As you move the figure across the drawing surface, it may erase parts of the picture as it passes over the screen. Don't be concerned-this is just a side effect of the animation process. When you press the button to choose the desired figure, the previous screen is redrawn, restoring any erased parts, and then the desired figure is overlaid on top of the picture. If you make a mistake, you can use the Undo option from the Picture menu (or simply press U), to restore the previous screen.

In Line mode, the first click sets one endpoint of the line. You move the other endpoint around with your pointing device. You see how the line will look as you move it around the screen. In Rectangle mode, the first click sets one corner of the rectangle. As you move the pointer, you are dragging around the diagonally opposite corner of the rectangle. In Circle mode, the first click sets the center of the circle. You move the pointer around to enlarge or contract the radius of the circle. The second click stamps down the figure. (Remember, you can always Undo the most recent drawing action.)

The Airbrush tool is handy for shading or blending colors. It randomly sprays out pixels within an 8 $\times 8$ zone centered around the pointing arrow. The longer you stay in one place, the more paint is sprayed down. If you move around while spraying, you get a series of random dots. This approximates the behavior of a real airbrush. Again, the first click starts airbrush mode, and a second click exits airbrush mode, restoring floating cursor movement. As with Draw
mode, lifting the stylus from the tablet surface implies you want to stop the airbrush and go back to moving the cursor.

Use the Paint tool carefully. It's used to fill in an enclosed area of the screen. For example, you could draw a rectangle first, then fill it in. The paint floods out of the cursor position, and doesn't stop until it touches areas of the same color. You can only fill an area bounded by the same color as the current drawing color. If you attempt to fill with a different color, the paint overflows the container, possibly filling the whole screen. However, if you remember to press $U$ before you start another drawing action, no harm is done.

You can use the keyboard shortcuts D for Draw, L for Line, R for Rectangle, C for Circle, A for Airbrush, and P for Paint.

Figure 3: The Picfure Menu

## The Picfure Menu

The Picture menu affects the overall screen canvas. Use Undo to restore the previous screen. The screen is saved in a buffer before any drawing command changes the screen. Undo copies this buffer back onto the screen, restoring the previous screen and erasing the most recent change. Of course, Undo can only undo the most recent action, and you can't go back to the way the screen was before you performed the Undo-you can't undo an Undo.

The New option simply erases the screen. Be careful-it doesn't ask "Are you sure?" first.

Use Quit to exit the program. You could, of course, simply turn off the machine, but Quit is somewhat more elegant. Once you're back in BASIC, you can type SYSTEM to exit to DOS.

The Save command stores your picture on disk. Open restores a pre-
viously saved screen. After you select Open or Save, a box pops up in the center of the screen, prompting you to enter a filename. You can enter any legal PC-DOS filename, including a path prefix, such as A: or B:. This is the name that your picture is stored under. After you Save a picture, you can use Open to read this picture back onto the screen.

If you don't use an extender, as in FLOWERS.ART, an extender is added for you. The extender is made of the characters PI (for picture) and the number of the graphics mode used: 1 for SCREEN 1,320 $\times 200 ; 2$ for SCREEN $2,640 \times 200$, and 5 for the PCjr 16 -color $320 \times 200$ mode, SCREEN 5.

So a picture saved while in 640 $\times 200$ mode would have the characters .PI2 appended to the filename. This extender is added for both Open and Save. If you attempt to Open the picture FLOWERS while in $320 \times$ 200 mode, it actually searches for FLOWERS.PI1. However, if you're in $640 \times 200$ mode, it searches for FLOWERS.PI2. This prevents you from loading a picture saved in one graphics mode onto the screen of another graphics mode. If you want to defeat this, either always use an extension, as in FLOWERS.ART, or append the appropriate .PI extension. If you're loading a picture saved as FLOWERS.PI1 onto the $640 \times$ 200 screen, you need to enter the filename FLOWERS.PI1 to prevent it from searching for FLOWERS.PI2.

If a disk error occurs, another box pops up showing you the DOS error code, and it prompts you to press either R for Retry or C for Cancel. If the error is something you can immediately correct, such as inserting a disk, you can press $R$ to retry the disk operation. Otherwise press $C$ to cancel the operation, then figure out what you did wrong before again selecting Open or Save.

Next month, we'll show you how to use the BLOAD command to load one of these pictures from within your own programs. If you can't wait, examine the Open and Save routines at lines 2100 and 2170.

The keyboard shortcuts for the Picture menu are ${ }^{\wedge} \mathrm{N}$ for New, O for Open, S for Save, and ' Q for Quit (remember that ${ }^{\wedge}$ means to press CTRL as you press the indicated key).

## Choosing Your Preferences

The Preferences menu lets you select various special options. The first three entries: $320 \times 200,640 \times$ 200 , and $320 \times 200 \mathrm{PCjr}$, let you pick which graphics mode to use. (You should choose your mode before you begin drawing; the drawing area is erased when you change modes, so any drawing will be lost.) The $320 \times 200$ mode gives you four colors to work with. In this mode, you can choose either of two color palettes: cyn/mag/wht (cyan/ magenta/white), or red/grn/yel (red/green/yellow). The latter options are ghosted in all other modes.

The $640 \times 200$ mode gives you more horizontal density for fine detail, but you can only choose between black and white. On the PCjr only, you can select the $320 \times 200$ PCjr mode and get 16 colors for vivid, realistic (or surrealistic) paintings.

## Figure 4: The Preferences Menu

The Bkgd color option switches to a different background color. Each time you select it, the background color changes to the next in a series, 16 colors in all.

Some of the Preferences items have keyboard shortcuts: B for Bkgd color, K for Keyboard, and J for Calibrate.

## BASIC Shortcomings

This program was an experiment of sorts, an attempt to discover if techniques such as pull-down menus can be achieved in BASIC. I knew from the beginning that BASIC's relatively slow speed (as compared to machine language or compiled languages) would be the limiting factor. In particular, using a $30,000-$ byte array for an Undo buffer causes a short delay the first time any routine is activated. The first time you try to move the cursor,
select a drawing tool，change col－ ors，select a menu，etc．，there is short delay as the huge array is shifted downward in memory to make room for new variables as they are encountered．This problem could be eliminated by referencing every variable in the program before the array is dimensioned， but this is really more trouble than it＇s worth．

The innermost，core routine in this program is the subroutine at line 20000 ，used to check for the ＂mouse＂position．It adapts to the keyboard，joystick，and touch tab－ let，checks for keyboard shortcuts， scales the values to the current screen resolution，and keeps these coordinates in bounds．All this checking in such a commonly called routine is bound to slow things down．If you are using only one pointing device or one graphics mode，you may want to consider streamlining this routine to speed things up．

## Screen Machine II

# Loading And Linking Commodore Programs 

# Part 5 The Commodore 128 

Jim Butterfield, Associate Editor

This month's installment concludes the series by discussing load/link techniques on Commodore's newest eight-bit computer, the 128. As you'll see, the 128's powerful BASIC has simple, built-in commands to perform jobs that require programming tricks on earlier Commodore computers.

There are three major ways to connect programs together. Chaining allows several programs to perform a job, each program continuing the work that a previous program has done. Load linking enables one program to call another, with the new program starting fresh on a new task. Overlaying allows a main program to call in supplementary material, such as machine language subroutines, data tables, or additional screens. All these techniques are easy on the Commodore 128 in 128 mode. For 64 mode, of course, you can use the techniques explained in previous articles in this series.

## Chaining

A program that is chained is broken into separate modules, and each part runs separately. The programs may proceed in a specific order; for
example, an input program may be followed by a sorting program and then an output program. Or a menu program may call in other programs that you request.

The 128 's DLOAD command makes disk chaining extraordinarily easy. If a program executes the statement DLOAD"THISPROG", the computer loads and runs the program named THISPROG. Variables from the earlier program are preserved, so the new program can continue where the old one left off.

The chaining pitfalls of earlier Commodore machines don't apply to the 128 . Because the 128 stores the BASIC program text in a different bank of RAM from the working values (variables, strings, and arrays), there is no danger that DLOAD will interfere with variables. The new program simply replaces the old one.

By the way, the 128 has no static strings; all strings, whether static or dynamic, are safely stored in bank 1.

Let's revise the rules for wellchained programs on the 128:

- It doesn't matter whether the first program is bigger or smaller than subsequent programs.
- Strings, variables, and arrays are passed from program to program.
- If you use DEF FN definitions, redefine them in each program module.
- Arrays should be DIMensioned only once, preferably in the first program.

## A Short Example

Let's write the first of a small series of Commodore 128 programs which chain together. We'll call our first program START, and it assumes that you want to record grades for eight students.
$11 \varnothing$ PRINT "SIMPLE GRADEBOOK DEMO"
$12 \varnothing$ DIM NS (15) , M(15)
$13 \varnothing \mathrm{~N}=8$
140 FOR J=1 TO N
$15 \varnothing$ PRINT "STUDENT"; ${ }^{\prime}$;
160 INPUT "NAME";NS(J)
17ø INPUT "SCORE"; M(J)
180 NEXT J
$19 \varnothing$ DLOAD "MENU"
When the program runs to this point, we have data on eight students. Save the program using the filename START.

Now let's enter the menu program. Type NEW and enter this:

[^1]```
12ø PRINT "1. CALCULATE AVE
    RAGE SCORE"
13\emptyset PRINT "2. CALCULATE HIG
    H/LOW SCORES"
140 PRINT "3. QUIT"
15\emptyset PRINT
160 INPUT "YOUR CHOICE (1-3
    )";
170 ON C GOTO 300,310,320
180 GOTO 160
3øø DLOAD "C.AVG"
31\varnothing DLOAD "C.HIL"
32ø END
```

Note that line 300 won't run into line 310, nor 310 into 320. The moment the program executes DLOAD, the new program loads and begins running. After checking this program closely, save it on disk with the filename MENU. (The name is important; don't substitute any other filename.)

Now type NEW and enter this program:

```
1ø\varnothing PRINT
110 A=\varnothing
12\emptyset FOR J=1 TO N
130 A=A+M(J)
140 NEXT J
150 PRINT "AVERAGE SCORE FO
    R";N;"STUDENTS =";A/N
16ø PRINT
17ø DLOAD "MENU"
```

Check this closely and save it as C.AVG. Again, the filename is important. Now type NEW and enter this program:

```
10ø PRINT
110 H=M(1):L=M(1)
120 FOR J=1 TO N
13ø IF H<M(J) THEN H=M(J)
140 IF L>M(J) THEN L=M(J)
150 NEXT J
160 PRINT "HIGH SCORE WAS";
    H;"BY:"
17ø FOR J=1 TO N
180 IF H=M(J) THEN PRINT N$
    (J)
190 NEXT J
2øø PRINT "LOW SCORE WAS";L
    ;"BY:"
210 FOR J=1 TO N
22ø IF L=M(J) THEN PRINT N$
    (J)
230 NEXT J
24ø PRINT
25ø DLOAD "MENU"
```

Again, check your typing closely and save it as C.HIL to complete the set.

Now you can experiment with chaining on the 128 by loading the first program (filename START). Note that this program is smaller than both MENU and C.HIL. On earlier Commodore computers, that would be a problem. But it doesn't matter on the 128 .

## Load Linking

Chaining links one program to the next while keeping the first program's working values intact. That's useful when you're continuing a calculation. But sometimes you'd rather throw away these values, allowing the newly loaded program to start fresh. The RUN command does exactly that. No fuss or bother-just specify the appropriate program name and you're in business. the old variables disappear, the pointers are reset, and the new program starts running.

To illustrate, let's write two very simple programs and use a menu program to select which one to use. Type NEW, then enter this simple square root program:
$1 \varnothing \varnothing$ PRINT "TABLE OF SQUARE \{SPACE \}ROOTS"
$11 \varnothing$ FOR $J=1$ TO $2 \varnothing$
$12 \emptyset$ PRINT J, SQR(J)
$13 \varnothing$ NEXT J
You can try running the program if you want. Save it with the filename SQUARE.

Now type NEW again and enter this simple cube root program:

```
10\emptyset PRINT "TABLE OF CUBE RO
    OTS"
110 X=1/3
12\varnothing FOR I=1 TO 2\varnothing
130 PRINT I, I \X
140 NEXT I
```

Again, you might like to try running the program. Save it with the filename CUBE. Type NEW again and enter this simple 128 loading program:

```
1Ø\emptyset DATA SQUARE,CUBE
110 READ AS(1),A$(2)
12ø PRINT "WHICH ROOTS DO Y
    OU WANT--"
130 FOR J=1 TO 2
140 PRINT J;AS(J)
150 NEXT J
160 INPUT "WHICH (1 OR 2)";
    N
17\emptyset IF N<1 OR N>2 GOTO 12ø
18ø RUN (AS(N))
```

Note the syntax of the RUN command. If you don't specify a drive number, the computer assumes you want drive 0 . If you want to run a program on a disk in drive 1, you would add ,D1 to the end of the filename. And if you want to use a variable for the filename (as shown above), it must be enclosed in parentheses.

When you run the menu program, it loads and runs SQUARE or

CUBE as selected. When the new program runs, all the old variables are scrapped. The second program starts fresh.

## Overlaying

This technique brings in extra material to accompany a BASIC program. It might be a machine language routine, a screen, sprite shapes, or data tables. Whereas chaining and load linking move from one BASIC program to another, overlaying lets the same BASIC program continue with new data in memory.

On the Commodore 128, BASIC 7.0's BLOAD command can bring in the material with no problems. It loads the file, and the BASIC program continues with the next statement. It's quite straightforward, especially compared to the gyrations required on earlier Commodore machines.

However, you must take care not to BLOAD information into the same area of memory occupied by the BASIC program itself (a crash usually results). BLOAD lets you specify a load address, but it's usually convenient to BLOAD a file into the same memory area from which it was saved.

Here's a quick example. First, let's set up a short machine language routine that prints a string of characters. Type NEW and enter this program:

```
10ø DATA Ø,26
110 DATA 162,65
120 DATA }13
130 DATA 32,210,255
140 DATA 232
150 DATA 201,90
160 DATA 144,247
170 DATA 169,13
180 DATA 76,210,255
190 A=18
2øø FOR J=1 TO A
210 READ X
22ø T=T+X
230 NEXT J
240 IF T<>2525 THEN STOP
25ø RESTORE
260 DOPEN#8, "ML, P",W
27ø FOR J=1 TO A
280 READ X
29ø PRINT#8,CHR$(X);
300 NEXT J
310 CLOSE 8
```

Be sure that line 290 ends with a semicolon. Then run the program. If it stops at line 240, there's a typing error in one of the DATA statements. Otherwise, it creates a oneblock machine language routine on
disk called ML. As we'll see in a moment, this routine prints the alphabet on the screen when called into memory.

Here's our main program, which loads the ML module we just created:

```
106 BANK 15
110 BLOAD "ML"
12\emptyset PRINT "HERE IS THE ALPH
    ABET---"
130 SYS }665
140 PRINT "HERE IT IS AGAIN
    ..."
150 SYS 6656
160 PRINT "THAT'S ALL."
```

BLOAD just brings the ML routine into memory and makes it available to the BASIC program. Simple and effective.

Overlays are popular with machine language programmers on the 128 partly because they are so easy to do and partly because of the mobility of BASIC programs. Depending on recent graphics activities, a BASIC program might start at address 7169 (the usual place) or at 16385 (if a graphics area has been allocated). Rather than puzzle over how to fit a machine language routine into memory with these uncertain locations, many programmers use an overlay. That way they know where the routine loads, even if they're not sure where the BASIC program might be.

Compared to the complexity of earlier Commodore computers, these techniques are a snap on the Commodore 128 in 128 mode. Just remember: DLOAD for chaining, RUN for load linking, and BLOAD for overlaying.

# Apple ProDOS Catalog Sorter 

William J. Coohon

Here's a short utility program that helps you organize your floppy disks by displaying or printing sorted directories. It works on any Apple II-series computer with ProDOS.

Sometimes, locating a particular program or file within a large collection of disks is like searching for a contact lens in a bowl of waterespecially when any list of your disk directories will inevitably be outdated and in no particular order. "ProDOS Catalog Sorter" helps you eliminate the confusion by sorting ProDOS directories and listing them on your monitor or printer.

Type in the program below and save a copy before running it for the first time. There are two options to consider when typing Catalog Sorter: date and time stamping, and printer set-up. Stamping the date and time on listings is extremely useful for keeping track of how current (or how old) the information is. If your Apple doesn't have a clock, you may remove certain lines from Catalog Sorter or use the date/time-setting program found in the "Reader's

Feedback" column in November, 1985 COMPUTE!. Without the date and time, the program prints zeros. To remove this feature, delete lines 280-320, 345, 445, and 780.

You can also determine how your printer should generate hardcopies of the sorted directories. My direstory listings are printed at 17 characters per inch with 8 lines per inch spacing. That way, they can be trimmed down to fit neatly inside a disk envelope or storage case. The printer control characters for an Apple Imagewriter are set up in line 440. If you want to substitute your own printer options, simply alter these codes. If you want your printer to use its defaults, delete line 440 completely. The variable P in line 440 is set to a value of 1 to allow the program to reset the printer options later in line 560, which may also have to be altered for other printer control characters.

## Sorting Directories

When you run the program, Catalog Sorter prompts you for drive number 1 or 2 (to exit the program at this stage, simply enter 0 ). Next, you are asked whether you want
the directories sorted．Type N to disable sorting；any other response sorts your directories in alphabeti－ cal order．When might you want to disable sorting？Sometimes pro－ grams or files are grouped under directories logically，according to their respective functions．But other files－for instance，monthly finan－ cial data－might be organized chro－ nologically．Sorting such files alphabetically would make the grouping less meaningful．

After reading the disk directo－ ry，the program asks if you wish to view the listing on your screen or route the output to your printer．It tells you which directory is being sorted（if you choose to sort），then prints the list and moves on to the next directory（if any others exist）． Multiple directories are read，sort－ ed，and listed separately to main－ tain the order of the directory hierarchy．The bottom line of the directory list indicates how many disk blocks are free，how many are used，and the total available（see figure）．When all directories on a disk are read，sorted，and listed，the program gives you the option to quit or repeat the process．

If the directory list is displayed on the screen，it appears in the same format as if you typed Pro－ DOS CATALOG command－in 80 columns（note that the abbreviated CAT command uses a 40 －column format）．This is rather difficult to read on a 40 －column display，so an 80 －column screen is recommended
unless you＇re interested mainly in the hardcopy listings．Line 260 sets up S $\$$ to switch to the 80 －column screen，assuming that the 80 －column hardware is addressed at slot 3 （the normal slot for the IIe and IIc）．If you wish，you can modify Catalog Sorter to display only 40 columns on each line：Change the PR\＃3 in line 260 to PR\＃0．

## Apple ProDOS Catalog Sorter

# Mandelbrot Graphics For Commodore 

Steven M. Thorpe

A mathematics phenomenon known as the Mandelbrot set can provide the basis for some stunning computer graphics. The following programs make it possible to generate a wide variety of colorful high-resolution images which can be saved on disk for future viewing. The programs work on any Commodore 64 (or 128 in 64 mode).

One of the most beautiful features of the Commodore 64 is its multicolor bitmap mode, which lets you create detailed high-resolution images using several colors. We're all familiar with the many drawing programs that work like video paint boxes, letting you draw directly on the screen. But the computer can create beautiful, highly intricate images all by itself, using relatively simple mathematical methods. "Mandelbrot Graphics For Commodore" allows you to generate interesting hi-res pictures, save them to disk, and reload them at any time.

## Creating Screens

Type in and save Program 1. When you run the program, it immediately clears the hi-res screen and begins to draw an image based on the Mandelbrot set (see below). You'll need to be patient: A full-screen hires image takes a long time to create. Although the program uses machine language routines to clear the hi-res screen, the drawing computations are done in BASIC.

In multicolor bitmap mode, up
to four different colors can be displayed in each character position. Distortion occurs if a program calls for too many colors in a single position. Since you can have only one screen background color at a time, each character position is actually limited to three independent colors. While this may seem a severe restriction, spectacular graphics are still possible. Program 1 selects an available color memory source (not yet used in the current character position unless used for the current color), and then sets the appropriate color code and bit pattern to display that color.

If you're impatient for results and don't mind viewing a smaller image, replace lines 180 and 190 with these lines (be sure you've saved the original version of the program before you make this modification):
180 FOR X $0=$ XL TO XR STEP (XR $-X L$ )/ 159*2
190 FOR $\mathbf{Y}=\mathrm{YT}$ TO YB STEP $(\mathrm{YB}-\mathrm{YT}) /$ 199*2

With this change, Program 1 draws an image about one-fourth the size of the screen, in roughly one-fourth the time it would take to draw a full-screen picture. To change back to a full screen, retype lines 180 and 190 as listed in Program 1. This can be useful when modifying the program to produce different results. You can view the results in a reduced scale to save time, then draw it at normal size to be saved to disk. Press RUN/STOPRESTORE if you need to break out of the program.

The variables $X L$ and $Y B$ play a crucial part in defining what the final image looks like. XL sets the left boundary of the Mandelbrot set and YB sets the bottom. Similarly, XR defines the right boundary and YT defines the top. By changing the values of XL, YB, and SR, you can "zoom in" for a closer look at any given area of the Mandelbrot set. You don't need to worry about the value of YT: The program automatically gives YT the value needed to shape the screen image correctly.

Line 170 contains color codes used for various parts of the image. Changing these numbers alters the colors used in the display (see your user's manual for an explanation of color codes). Lines 222-230 shape the zones for each different color. In line 120, the variable SM determines the spacing between different colors, and CT controls how much detail is shown. Remember, using too many colors in zones of rapid color change can lead to excessive color distortion. Together, the variables SM and CT affect how long it takes to complete a Mandelbrot image.

## Invisible Lines Of Power

Programs 2 and 3 contain modifications for Program 1 which generate different displays based on the unseen forces of nature. To use these programs, you must already have a copy of Program 1. To enter Program 2, first load Program 1 into memory, then type in the lines listed in Program 2 (they will replace lines $100-240$ of the original

"Mandelbrot Graphics For Commodore" creates detailed hi-res images based on an unusual mathematics technique.
program). When that's done, save the program using a different filename from the one you used for Program 1

Program 2 uses the color schedule to paint patterns that resemble the magnetic lines of force between two wires charged with electricity. Displays of this type make it easier to visualize forces such as electromagnetism, which are invisible to the naked eye, yet have a profound effect in the world around us. Of course, you can enjoy the displays even if you don't understand the scientific concepts involved in these simulations.

You can also modify Program 2 to produce different effects. Change the values of variables I1 and I2 to see what the magnetic pattern is like for various current levels. For instance, if you set I1 to 25 and I2 to -100 , the program displays an opposed current flow with one current four times as large as the other. Larger current levels cause closer flux lines, more detail, and a greater chance of color distortion.

To enter Program 3, load Program 1, type the lines listed for Program 3, then save the entire program under a unique filename. Program 3 simulates another invisible, yet powerful force of naturethe interaction of gravitational forces between the earth and the moon. The black region on the right is the zone of gravity equal to that at the surface of the moon. The program accurately draws the moon to scale relative to the gravitational potentials in effect.

Line 120 of Program 3 positions the earth and moon relative to the upper left-hand corner of the screen, using an $x, y$ coordinate scheme in which the screen has

This image simulates the lines of electromagnetic force surrounding two electrical conductors.
horizontal positions $0-159$ and vertical positions 0-199. The earth can be shown by assigning it a value on the screen. You can create an interesting image by placing the earth at coordinates 53,99 and the moon at coordinates 106,99 .

The variable F determines which color is plotted. F represents the gravitational force (measured in Newtons) on a stationary one-kilogram mass. Variable DE represents the distance from earth, and DM signifies the distance from the moon. The region close to the moon was made one color because it has such a steep gravitational gradient that there would be excessive color distortion if it were not specially treated.

## Saving And Loading Screens

After you create a screen, it's easy to save it on disk for future use. Simply press S after the image is completely drawn. Before saving an image, make sure that the disk drive contains a disk with at least 40 blocks free. Three different memory areas must be saved in separate disk files to reconstruct the image accurately.

To avoid spoiling the image with a printed prompt, the program switches temporarily to a text screen to allow you to enter a filename (which should contain no more than 12 characters). The program then manipulates the name you enter to create distinct filenames for the three files necessary to store all the picture information. The prefix $M$ - is added to the filename you specified for the first file. This file contains the hi-res bitmap of the image. For the next file, the suffix $S$ is added in addition to the

This pattern is created by a program that represents the gravitational forces around the earth and the moon.

M- prefix. This file contains the screen memory for the image. Finally, for the third file, the suffix $S C$ is added in addition to the $M$ - prefix. This file contains the color memory for the image.

Choose your filenames carefully; the program erases any existing files with the specified filename before it stores the new files. Thus, if you accidentally reuse an existing name, you may overwrite a previously saved masterpiece.

After you enter the filename, the program switches back to the hi-res image while the screen is being saved.

Program 4 loads the stored image from disk and displays it on the screen. When you run this program, it asks you to enter a filename. Give the filename you specified when you saved the image with Programs $1-3$. Don't worry about the prefixes and suffixes; Program 4 takes care of these and loads all three files necessary to recreate the image.

## What Is A Mandelbrot Set?

Although Mandelbrot images have attracted wide interest as a means of generating graphics, the origin of these pictures lies deep in the realms of mathematics and engineering. In brief, certain engineering problems require the use of complex numbers. A complex number consists of two parts: a real part and an imaginary part. The real part of the number is like the numbers we use every day. For the imaginary part, special rules of multiplication apply. For instance, if you square the imaginary part of a complex number, the result becomes negative and real. Thus, imaginary numbers are often written in engineering calculations as a real
number multiplied by the constant $i$, where $i$ can be considered the square root of -1 .

The real and imaginary parts of a complex number can be plotted on a coordinate grid known as the complex plane. Benoit B. Mandelbrot, a researcher at IBM, discovered that points inside a certain region of the complex plane behave strangely when they are repeatedly squared and the result of each squaring is added to the original point. Some points get large rapidly, while their near neighbors grow slowly. Other neighboring points don't grow at all. As the process is repeated, these tendencies are accentuated. The region where these strange results occur is called the Mandelbrot set after its discoverer.

While Mandelbrot sets have certain practical applications, they can produce striking results when you translate the numeric values into different-colored points on a computer screen. These programs color each point on the hi-res screen according to how fast it grows during the iterative (repetitive) process. Computing the entire set requires an enormous number of calculations, so all of these programs take some time to com-plete-many hours in some cases. You may want to start a program running at bedtime so the picture will be finished by the next morning. (There's no need to leave the monitor on all night, of coursé.)

If you'd like to photograph a finished image, shoot the photos in a darkened room to eliminate screen glare. Load a single-lens reflex camera with medium-speed film (ISO 100 works well), mount the camera on a tripod, attach a cable release, aim the viewfinder squarely at the screen, and use a very slow shutter speed-no faster than $1 / 4$ second. If your camera has an automatic exposure mode or a built-in light meter, it should indicate a lens aperture of $\mathrm{f} / 8$ to $\mathrm{f} / 16$.
For instructions on entering these listings, please refer to "COMPUTEI's Guide to Typing In Programs" in this issue of COMPUTEI.

## s5 TALKING DISK

OVER 100 WORDS in vocabularies that you can put into your own programs！No extra hardware required．Sam－ ple programs include：
－Talking four－function calculator－choose English， Spanish，or German．
－Talking keyboard－letters and punctuation in English．
－Demonstration of voice editing．
The $\$ 5$ Talking Disk is available for Commodore 64，128， Atari $800,800 \mathrm{XL}, 130 \mathrm{XE}$ ，and Apple II＋（ 64 K ），Ile，and IIc． If you want to make your own vocabularies，in any lan－ guage or accent，then you must have a VOICE MASTER for processing speech input．VOICE MASTER lets you do much more：YOU CAN RECOGNIZE SPOKEN COMMANDS and WRITE MUSIC AS YOU HUM！And affordable too－under \＄90 including the headset and microphone．
Send $\$ 5$ for the talking disk．Prepaid orders only． Includes postage．（\＄7 outside USA，Canada，and Mex－ ico．）Information on VOICE MASTER will accompany your disk．Or you can call or write for VOICE MASTER information separately．Please specify computer make and model with your order．

# It Only Takes Two To Make Music 

For 20 years Paul Lehrman has dreamt about becoming a composer. "But," he says, "serious composers often end up starving to death."

Paul has a lot of experience in the music industry-as a musician, recording engineer, and most recently as vice president of Southworth Systems, the makers of Total Music, a MIDI music program for the Apple Macintosh. "I'm not a serious composer," he says. "I'm a pop guy. But I want to help serious composers make music.'

Paul is convinced that computers can help composers. To prove this, he recently did what no one has done before: He created an entire album of music with a personal computer. His album, The Celtic Macintosh, consists of traditional and contemporary Irish and Scottish jigs, reels, hornpipes, airs, and laments. It took him less than three weeks, start to finish, and cost him a little under $\$ 100$. (He had to buy five floppy disks, a VHS videotape, and rent a digital tape converter.)

Why Irish and Scottish folk songs? St. Patrick's Day was coming, and Paul's Irish-American friend Sharon Kennedy, a storyteller, asked him to put together "something quick" that she could play over the PA system as background music at the annual St. Patrick's Day Concert in Brookline, Massachusetts. She was so happy with the result that Paul decided to make a whole album and sell it at the concert.

## A Home Studio

Paul's recording studio was in his living room. Each morning he would get up at 10:00 a.m., shower, eat breakfast, walk the eight steps to his studio, and go to work-in jeans and a bathrobe. His instruments consisted of three synthesizers (a Kurzweil K250, a Yamaha DX7, and a Casio CZ-101), a drum
machine (Roland PR-707), a digital effects processor (Lexicon PCM70), a keyboard mixer, and the Fat Mac running Southworth's Total Music software.

Paul did not look especially historic or impressive sitting alone in a bathrobe in his living room typing on a Mac and flanked by a few keyboards. But looks are deceiving. To really appreciate what he has done, you have to listen to his album. You hear woodwinds, an accordion, a hammer dulcimer, guitars, an acoustic piano, penny whistles, drums, trumpets, a harp, flutes, tympani, and many other in-struments-some of which he invented. And, thanks to the PCM70 (which doubles as a reverberator), the songs sound as if they were played in all sorts of places-from a small, cozy bar to a grand concert hall. I was totally fooled. It is a masterful audio illusion. But it is also fine music.

Using the Mac, Paul called up instrument sounds on each of the keyboards, played them on the Kurzweil (which acted as his master keyboard), and recorded them as a single track on a $31 / 2$-inch floppy disk. He replayed the tracks, polished them, then overdubbed new tracks on top of the old. By layering the tracks together, he created the illusion of an entire band or orchestra.

With the press of a button, the computer played all the instruments while Paul taped them on a VHS video recorder. To make the recording sound professional, he used a Sony PCM (pulse code modulation) converter he rented for $\$ 10$ a day to convert the analog sound signal into a digital signal. When recorded on the videotape, this digital audio equals the sound quality of a compact disc.

Next he went to a local record duplication house, which copied
his master tape onto standard audio cassettes-50 at a time.

## Not Machine Music

"People expect music made by machines to sound like machine music," says Paul. "I made this album to disprove that. I used the computer to do the things it does well, and made it play the kind of music I wanted to play. I deliberately left in things that some people might call mistakes-little timing things and grace notes. I could have fixed them, but I didn't. I wanted the music to sound like it was made by a human being. Without that human element the music becomes rhythmically perfect all the time. It sounds boring, robotic.
"I wanted to show that a composer could set up everything in his living room and not spend a lot of money. He can create and record his own music all on his own. A system like this cuts all the complications and red tape separating a composer from his audience. Now there is no one between them.
"When I was a kid I went to see Mary Martin do a concert in New York City. I remember she sang a song called 'It Takes Three to Make Music'-one to write, one to play, one to hear. That equation is changing. Now, in a very real sense, the person who writes and the person who plays can be the same person. So it only takes two to make music. And we're not talking about playing a piano, either. We're talking about having an entire orchestra at your disposal. Any kind of orchestra, with any kind of instruments."

To learn more about Paul's system, write to Paul D. Lehrman, 31 Maple Ave. Apt. \#1, Cambridge, MA 02139. To get a tape of The Celtic Macintosh, send $\$ 10$. To learn more about Total Music, write Southworth Music Systems, Inc., Box 275, RD 1, Harvard, MA 01451.

## Metaphorical Computing

Every time we use a computer, we are working with metaphors. In some cases the metaphor is obvious, and in others it is not. A game, for example, might provide us with a model of a city through which we have to navigate without being caught by the bad guys. Rationally, we know there is no city or bad guys, but this metaphor lets us move beyond the computer to the application itself-the computer becomes the mirror of the mind's eye.

This aspect of the computer is what makes it so useful. Metaphors like desktops, menus, and windows can make computing appear more like "real" activities. Those who prefer command line interpreters to desktops are merely expressing a preference for one metaphor over another. None of this matters to the machine. As far as the computer is concerned, code is code and bytes are bytes.

High-level computer languages are programs and are therefore metaphors as well. As the noted computer scientist Edsger Dijkstra says in his book A Discipline of Programming: "There are two machines-the physical ma-chine-the one that you pay for, that breaks down, that takes space on your desk. Then there is the abstract machine-defined by the functions the machine is to perform."

As programmers, we trust that the abstract machine is implemented in the physical machine. In fact, it might not be. For example, a program could accept 6502 machine language and convert it to run on a 68000 microprocessor. From the programmer's perspective, the computer is a 6502 . The point here is that, even at the most basic level of programming, one cannot escape from metaphors.

## Generations Of Languages If computation is metaphorical at

the machine level, it becomes even more so as we move to higher-level languages. In assembly language, for instance, the metaphor of the machine is often expanded to include instructions that the computer cannot execute directly. Programmers call these macros, or macro instructions. A macro that simulates a missing multiplication command greatly simplifies the programmer's task.

At the first two levels of computer language (machine and assembly), the metaphor pertains to the machine itself. At this level it is the program's purpose to instruct our computers. Once we move to high-level languages like BASIC, FORTRAN, COBOL, LISP, PROLOG, Forth, and Smalltalk, it becomes the computer's task to execute our programs. This may seem like a subtle distinction, but as we shall see, it is not.

I have come to believe that the major differences between various high-level languages are not to be found in their syntaxes, grammars, or vocabularies, but in their metaphors.

A Pascal programmer, for example, sees a program as a collection of procedures, each of which produces some effect. A LISP programmer sees a program as a collection of functions that output results in much the same manner as mathematical operations. A PROLOG programmer sees a program as a collection of assertions and rules that the computer can use as needed to respond to a query.

Now we can begin to see why it's so difficult to write major application programs. The programmer has the task of creating one metaphor out of another one. This is why multilingual programmers often spend some time deciding which language to use before writing any code.

The trick to making programming easy is to make the metaphor of the language match that of the application.

## Construction Sets

Some languages do this quite well. The ease with which a user can create new pinball games with Pinball Construction Set is a result of the program's use of the same metaphor, whether a game is being constructed or played.

Other construction set languages (including Loderunner and any good spreadsheet program) have become immensely popular. Their popularity arises from ease of use, and this is a direct consequence of the consistency of the metaphor as one moves across the boundary from programming to executing a program.

While construction sets have great value, they also have a strong limitation. They are not generalpurpose programming tools. One cannot build a word processor using Pinball Construction Set or a music program with Multiplan.

The closest we've come to gen-eral-purpose direct-manipulation languages is with products like Filevision, a Macintosh-based visual database program. I've used Filevision since 1984 as a tool for creating instructional software. But even Filevision (which was never intended to be a language) has its limitations.

The key to constructing a general-purpose direct-manipulation language is to find a "meta-metaphor"-a metaphor that encompasses all application metaphors. Does such a metaphor exist? This question is being asked by those of us who are exploring direct-manipulation programming. So far, the answer is not clear.

In the meantime, metaphors be with you.

## Turning Apples Into Oranges

Sometimes it seems as if BASIC is overpopulated with a nearly endless collection of string-handling functions. We've already looked at LEFT\$, MID\$, RIGHT\$, CHR\$, ASC, and LEN, not to mention operators for adding strings together and making logical comparisons. Yet, we've barely scratched the surface of what can be done with strings in BASIC. The reason for all these functions is that programmers keep demanding more and more flexibility for manipulating text in their programs. One of BASIC's early predecessors, a language called FORTRAN, was very strong on mathematical functions, but rather weak when dealing with strings. From the very beginning, BASIC has sought to improve in this area.

Two interesting string functions we haven't covered so far are VAL and STR\$. These two functions, common to virtually all BASICs, are opposites of each other. STR\$ lets you convert a number into a string, and VAL lets you convert a string into a number. For example, look at this program:
10 DIM AS(10):REM This line for Atari only
$20 \mathrm{~A} S=" 123$ "
30 PRINT AS
$40 \mathrm{~A}=\mathrm{VAL}(\mathrm{A} \$)$
50 PRINT A
$60 \mathrm{~A} \$=\mathrm{STR} \$(\mathrm{~A})$
70 PRINT AS
When you run this program, the result is:
123
123
123
So what? you say. We could get the same result by deleting lines 30-70 and simply substituting PRINT A\$: PRINT A\$:PRINT A\$.

But the result would not be the same. Although PRINT A\$ in line 30 prints the number 123 on the screen, it's printing the number as a character string, not a numeric value. You can't tell one from another when they're printed on the screen,
but the difference is important and matters very much to BASIC. If you attempt a statement such as $\mathrm{A}=\mathrm{A}+$ " 123 " or A $\$=A \$+123$, BASIC reports some sort of type-mismatch error. Character strings and numeric values just don't mix.

That's why there's VAL and STR\$. As shown in line $40, \mathrm{~A}=$ $\operatorname{VAL}(A \$)$ takes the number " 123 " stored as a character string in A\$, converts it into the corresponding numeric value 123, and stores it in the numeric variable A. Conversely, the statement $\mathrm{A} \$=\operatorname{STR} \$(\mathrm{~A})$ in line 60 takes the number stored as numeric value 123 in A, converts it into the character string "123," and stores it in the string variable $\mathrm{A} \$$. In short, VAL and STR\$ let you turn apples into oranges and back again.

## Easier Input

An interesting trick, you say, but what's the purpose? True, VAL and STR\$ aren't exactly the most heavily used functions in the BASIC language. Instead, they're like Allen wrenches-once a year when you need them, nothing else will do.

For instance, recently I wrote a short program to experiment with a new computer's sound capabilities. The program asks the user to enter a phone number, then dials the number by playing Touch-Tones through the monitor speaker. To determine which Touch-Tone frequencies to play, I needed to extract each digit in the phone number as numeric data. But to make it as easy as possible for the user to enter the phone number, I wanted the program to accept the keyboard input as a character string. That way, people can type in the phone number any way they want: (919) 5551212, or 919-555-1212, or 919555 1212, etc. A statement such as INPUT A\$ accepts all those variations. But if the program used INPUT A, the phone number would have to be entered as 9195551212, or an
error would result.
So, VAL comes to the rescue. Once the phone number is entered in A\$, the program loops through the string, converting digits from 0 to 9 into numbers with VAL. The numbers are then passed along to SOUND statements which play the tones. Spaces, hyphens, parentheses, and other characters are ignored. Here's a simplified version of the routine:

100 FOR N=1 TO LEN(A\$)
110 IF ASC(MID\$(AS,N,1))<48 THEN 150 120 IF ASC(MID $\$(A \$, N, 1))>57$ THEN 150 $130 \mathrm{~A}=\mathrm{VAL}(\mathrm{MID} \$(\mathrm{~A} \$, \mathrm{~N}, 1))$ 140 REM SOUND statements to play Touch-Tones here... 150 NEXT N

This routine conveniently demonstrates several string-handling techniques we've covered in the past few columns. Line 100 sets up a FOR-NEXT loop by using the LEN function to measure the length of A\$; this determines how many times the loop repeats (one loop for each character in A\$). Lines 110 and 120 use the MID\$ function to examine one character at a time in $\mathrm{A} \$$; if the ASC function discovers that the character is less than the ASCII value of 48 (the number 0 ) or greater than the ASCII value of 57 (the number 9), the program skips to line 150 and makes another pass through the loop.

If a character in $\mathrm{A} \$$ is a number $0-9$, the program falls through to line 130. Here, the VAL function converts the character into a numeric value and stores it in A. Line 140 is where the SOUND statements to play the tones would be inserted. Line 150 then loops back to examine another character in $\mathrm{A} \$$.

You can adapt this trick to many of your own programs. Whenever you'd like to accept keyboard input as a string for maximum flexibility, just convert the string with VAL to the numeric input you're really looking for.

## Electronic Bulletin Boards: A Retrospective

Bulletin boards have been with us in one form or another for hundreds of years and will likely stay with us well into the future. Why? What's so special about bulletin boards, electronic or otherwise?

It's difficult to pinpoint when the first bulletin board appeared. Perhaps cave paintings were primitive bulletin boards. In the modern sense of a community communications media, the earliest bulletin board may have been the medieval practice of posting royal proclamations in the center of commerce, the town square.

The traditional bulletin board, with a wide variety of messages tacked to a freely accessible surface, abounds in our supermarkets, factories, offices, schools, laundromats, community centers, and city halls. These bulletin boards are more than just a way to give away kittens or sell tires. They make it possible for people with a message to reach out to the community as a whole.

## Electronic Thumbtacks

The thousands of computer-based bulletin board systems (BBSs) which are online today offer the traditional message posting and a great deal more. Imagine trying to maintain a series of communications with other people using a regular bulletin board at a supermarket. Driving to the store every time you want to leave or read a message makes extended communication via corkboard and notecard extremely inconvenient. Even if you make the trip regularly, a less than careful search of the posted messages may miss the very reply that was sought.

The fact that a BBS can be accessed remotely, without leaving one's home, makes an ongoing dialog between many parties a simple matter. A computer dedicated to running the BBS manages the mes-
sages; in addition to numbering and indexing the messages, it also automatically notifies its many users of messages intended specifically for them.

The first BBS was born of necessity in 1978. Microcomputers were just getting off the ground, and the first micronauts were few and far between. The four major enclaves of personal computing were located in California, Illinois, Texas, and Massachusetts. Although the computer clubs in these areas exchanged newsletters regularly, there was a decided lack of spontaneous interaction between the major groups and even within the groups themselves.

Ward Christensen and Randy Suess, both members of the Chicago Area Computer Hobbyist Exchange (CACHE), came up with the answer. They developed a program to run on a computer that was equipped with a modem hooked up to a phone line. The program turned the computer into an automated message system. Callers to the Computerized Bulletin Board System (or CBBS, as its originators referred to it) could leave and retrieve messages at any time of day. The CBBS was a huge success, and other clubs began pressing personal computers into service as bulletin boards.

## The Spread Of BBSs

CBBS was not a universal program. It was written for computers which used the CP/M operating system (Control Program for Microcomputers). Christensen and Suess wrote a widely publicized article describing the program and the structure of their system as it appeared to the person calling into the CBBS. Realizing that similar programs would be written for other types of computers, they proposed that the functions and commands used by the CBBS be standardized
for all BBSs. This would make it unnecessary for people to learn a whole new set of commands for each type of board they accessed.

Sure enough, BBS software for other popular systems soon followed. Craig Vaughn and Bill Blue created a program for Apple II computers called the People's Message System (PMS). Close on their heels was Bill Abney, who produced Forum 80 for the Radio Shack TRS-80, and Tom Giese, father of the Atari Message \& Information System (AMIS) for the Atari 400 and 800. Late in 1982, the first version of the Remote Bulletin Board System (RBBS) for the IBM was written by D. Thomas Mack and Jon Martin.

Aside from a message exchange, most BBSs offer a selection of public domain programs and other types of files. By using terminal software capable of receiving files via modem from a remote computer, callers can transfer (download) copies of these files from the BBS to their own machines.

Most of the free software available from BBSs consists of programs that computer enthusiasts like yourself have written and wish to share with other people. A plethora of games, word processors, spreadsheets, database managers, and terminal programs are available for the price of a phone call. Whatever your needs, you can acquire a respectable library of al-most-free software that will handle all but the most demanding tasks.

Next Month: Current Trends in Bulletin Board Systems.

## Tried And True Tools

In keeping with COMPUTE!'s programming languages theme for this month, I'd like to share some thoughts about programming in general and better use of the available languages in particular. I have long contended that, for most purposes, owners of Atari 400/800, XL, and XE computers have all the languages they need. You won't do parallel array processing with a 6502, no matter what language you use, but you can balance your checkbook, keep track of your mailing list, access online services via modem, write a book or two, and (of course) play some games. All of those applications and many more have been written with languages now available for the eight-bit Atari computers. What more can you ask for?

In a previous column I said it would be hard for most users to justify trading up to an ST, an Amiga, or whatever. If anything, I feel more strongly about that now. I still write this column using a good old Atari 1200XL (I like its keyboard best) and an Atari 825 printer (ancient history). Sometimes I wish for an 80 -column screen or a hard disk drive-keeping track of 200 floppies is not my idea of fun-but I can't justify the expense for the extra convenience.

The same is true when it comes to programming languages. Admittedly, I'm a language junkie. I love learning new languages and/or tricks with old languages. So it would seem that the ST would be a dream machine for me. Despite its youth, the number of languages either available or coming soon is phenomenal: several varieties of BASIC, Logo, Pascal, C, LISP, Modula-2, COBOL, FORTRAN, Prolog, Forth, and 68000 machine language. There are probably others, too.

## Old Machines,

 New ProjectsBut for owners of eight-bit Ataris, the situation is far from bleak. Though some of the language implementations are not as rich as those on the ST, we can enjoy Pascal, C, Logo, Action!, Forth, PILOT, 6502 machine language, and some extraordinarily easy-to-use BASICs.

Even though I've been using Ataris for six years now, I still see some interesting projects to doprojects that I've never done or which I think can be done better. A few examples: How about a terminal program written in Action! that is designed to work well with CompuServe's conference mode? Or a GEM-like interface for DOS? Or a combined spreadsheet/database written in BASIC XE and commented liberally so that even beginners can see the methods used? I know I'll never do all of these, but they are challenges I'd like to tackle.

## Rethinking The Problem

Moving to new languages on new machines is not always an advantage. For instance, in ST BASIC, strings cannot exceed 255 characters in length. Atari BASIC strings can be up to 32,767 characters long, if you have the memory available. (Yes, ST BASIC allows string arrays, but so do BASIC XL, BASIC XE, and Atari Microsoft BASIC.) There are many other examples.

Another factor is that the speed and power of the newer machines is of little advantage for some applications. Other than missing an 80column screen, I can use CompuServe or various bulletin boards just as well with my $\$ 100$ computer as I can with the company's $\$ 1,000$ machine. Besides, the modem for the $\$ 100$ computer is cheaper. And by the time you read this, Atari may have released its 80-
column adapter for the eight-bit line.

Suppose you're writing a program that does need more speed, however. What can you do other than buy a newer, faster computer? Well, you could buy a better, faster language. That's a lot cheaper than buying a new computer-for which you still might need an extra language or two. On the other hand, maybe you don't have to buy anything at all; maybe you just need to rethink your solution to the problem. Let me show you what I mean.

Program 1 is very similar to one which I found in a recent user group newsletter. The author was responding to a member's inquiry about writing a routine to shuffle a deck of cards. As you know, when BASIC gives you a random number, there's no guarantee it won't give you that same random number twice, perhaps even several times. For a quick example, type the following line and press RETURN:
FOR I=0 TO 9:PRINT INT(10*RND

## (0)):NEXT I

This asks for ten random numbers in the range 0 to 9 . Did you actually get ten different numbers? The odds are very much against it.

## The Super Shuffle

Program 1 demonstrates this problem by dealing out an entire deck of 52 cards. As each card is dealt (by suit $S$ and rank $R$, line 210), its spot in the C (card) array is marked. Then, if the random number generator picks that card again, the pick is ignored (line 230). The only things I added to the original routine are the counters ( C and T ) which count how many picks it takes to get each card and the entire deck. Can you guess how many picks it takes to get the entire deck? In 50 tests, it took a minimum of 128 picks and a maximum of 457 , with the average around 220 . The
result，as you＇ll see if you run the program，is that it can take as long as five or six seconds to pick a card．

Now look at Program 2，which does exactly the same job but never takes more than one pick to get the next card in the deck．It works by using a single string（CARD\＄）to represent the entire deck．When it gets a random number from 1 to 52， the program removes the corre－ sponding＂card＂from the＂deck＂ （lines 400 and 410）．The next time it picks a card，it gets a random num－ ber from 1 to 51 ．Each time the computer gets a card，the range of random numbers gets smaller．Sim－ ple．And it works by taking advan－ tage of the string operations in Atari BASIC．

The point of this exercise is to show that sometimes the best way to fix a slow or inefficient program is to rethink it and then rewrite it． I＇d be willing to bet that Program 2 on an eight－bit Atari runs faster than Program 1 on an Atari ST．If you have access to both machines， you might want to try it．And try improving your own programs． （Even while writing this column，I found a way to improve Program 2 even more．Can you find it？）

One last comment：Notice the readability of the two programs． Which one is cryptic and which one almost explains itself？Meaningful variable names can add a great deal of value to any program．

For instructions on entering these listings， please refer to＂COMPUTEI＇s Guide to Typing In Programs＂in this issue of COMPUTE！．

## Odd Facets Of GEM

This month we're going to explore a handful of quirks in the GEM desktop: things you can do to make your system more useful...things you can do to make your system crash! Since I'm a natural-born pessimist, let's start with the crash.

The bug I'm about to demonstrate infests the ROM (Read Only Memory) version of the TOS operating system. Even so, if you don't already have the TOS ROMs, get them today. The difference in overall system performance and capability is only a little short of great.

To see this bug, simply boot your system and bring up the Control Panel. Select either the date or time field. Then type an underline character (SHIFT-hyphen). Watch your system bomb. The only recovery is to press the reset button or turn off the power.

Problem: The Control Panel is a form of dialog box, and it uses what are known as editable text fields to display and let you modify the date and time. An editable text field is designed to restrict the user to typing certain characters. For example, the date and time fields of the Control Panel are editable fields which allow only numbers to be typed. Unfortunately, somehow a bug crept into the ROM-based TOS. Anytime you edit a numericonly field, typing the underline causes something nasty to occur. Editable fields for filenames have a similar, though usually nonfatal, problem.

Solution: A GEM application program that needs to accept nu-meric-only input from the user has two choices: (1) Use an editable field which allows any character and then validate the user's input after the dialog box returns; (2) Retrieve keystrokes one at a time, checking them on the fly, and print only the valid ones on the screen. The former solution is kind of ugly
because the user doesn't get immediate response to incorrect input. The latter solution is a lot of work. Take your pick.

## Modifying DESKTOP.INF

Many of you already know how to customize the GEM desktop so your preferences appear automatically when you boot up the ST. When you select the Save Desktop item under the Options menu, GEM saves a file to the disk in drive A called DESKTOP.INF which stores these preferences. You can rearrange the icons on the screen, change screen colors, resize the windows, and so on, and GEM remembers it all for you.

DESKTOP.INF is an ordinary ASCII file, so it can be modified with most text editors and word processors. This lets you personalize GEM even more. (See "ST Hints \& Tips," COMPUTE!, June 1986.)

The first thing we'll do is the easiest. Using a text editor or word processor that handles ASCII files, load and examine DESKTOP.INF. You should see one or two lines which contain the words FLOPPY DISK (among other things). These are the labels which appear beneath the disk icons. I usually rename the labels -Top-Disk- and Bottom-Disk. (I've used dashes here to show where I typed a space-magazine typesetting sometimes makes it hard to indicate spaces.)

Save the modified file back on disk in ASCII format. The next time you boot from that disk, the names should appear as you have modified them. Just for fun, sometimes I change the name of the trash can to Junk! or Garbage or something equally silly.

## Rearranging Files

There are even more interesting things you can do with DESKTOP.INF. If, like me, you have a
disk or subdirectory in which you do most of your work, you'll soon find that you can't see all of the filenames or icons on the screen at once. Although it's a minor nuisance, it always seems that the files (or, more likely, programs) which I want the most are always off the screen. How can we force them back on the screen? Preferably in the upper-left position?

One solution, since the default display mode under the Show menu is Sort by Name, is to name your favorite files AARDVARK.PRG or AAABASIC.PRG. But that's kind of messy. A better method might be to choose Sort by Date if you could change the file's creation date. But I think Mark Rose (of Optimized Systems Software) has hit upon the best scheme.

First, he chooses Sort by Type. Second, he renames his most-used programs so they have no type (filename extension) at all. Third, he loads DESKTOP.INF and adds a line or so. To figure out exactly what to add, look for a line in DESKTOP.INF similar to this:
\#G 03 FF *.PRG@ @
This line tells the desktop that all files which match the *.PRG specifier are GEM (G) program files. Now, let's say the program you want to appear at the top-left of the screen was called PASCAL.PRG and has been renamed to simply PASCAL. You would add this line to the end of the DESKTOP.INF file:
\#G 03 FF PASCAL.@ @
This tells GEM that PASCAL is actually a GEM-based program. Neat, huh? What's more, you can do this for several files. However, I do not recommend using the *. wildcard in such a line-general untyped files end up looking like programs, a dangerous practice. ©

## A Beginning Reading Program

When my youngest son was learning to read, I wrote lists of words for him to practice with. The word lists used a certain word ending coupled with various beginning letterssuch as AT, BAT, CAT, FAT, HAT, MAT, PAT, RAT, SAT, TAT, VAT, and THAT. After I wrote the same list several times, I realized this was another idea for a computer application.

Not only can the TI-99/4A print the words nicely on the screen, but with the TI Speech Synthesizer it can also speak the words aloud. This month's example program, "Reading Practice," takes advantage of this feature. Therefore, it requires both the TI Speech Synthesizer and the Terminal Emulator 2 command module. Insert the module and select 1 for TI BASIC to gain access to speech.

## Reading Practice

Notice line 154 in the program listing below. This OPENs the channel for speech, so any subsequent PRINT \#1 statement will speak the word. The words I selected for examples are all pronounced correctly by the speech synthesizer as they are spelled. If you add words, check their pronunciation; you may need to add a routine so the word is pronounced correctly.

If you want to run this program without speech, omit all statements that refer to file 1 or insert a REM in front of each of these commands. Another alternative is to make speech an option; insert IF-THEN statements before the speech commands.

Due to space limitations, I had to keep Reading Practice rather short. Feel free to add graphics, sound, and additional word lists. I included just a few for examples. You could also modify the program to offer the student various groupings of words.

When you run Reading Prac-
tice, you'll see a word ending in lowercase letters. To hear the word pronounced aloud, press the space bar. To go to the next word, press ENTER. The screen clears and you'll see a word with a beginning letter and that word ending.

The words are in the DATA statements starting at line 198. First there is a word ending, then all the beginning letters that go with the word ending and create real words. ZZZ indicates no more beginning letters for that ending. At the end of all the lists, @@@ indicates the end of data.

Lines 126-146 redefine characters to draw larger lowercase letters. Be careful typing the DATA statements; they contain the character definitions. If you have my program for lowercase letters (СомPUTE!, August 1983), you can take a shortcut. First, load that program and delete all the PRINT statements. Type RES 126,2 to renumber the lines. Then add the rest of the Reading Practice program.

Lines $20-110$ contain subroutines to draw the 26 letters of the alphabet. The variable R is the main row number and C is the column number. If a lowercase letter has an ascender or descender, more than one character is required to draw the letter. Line 174 goes to the proper subroutine for each letter in the word. Since there are 26 possible letters, I needed low line numbers to use a single ON-GOSUB statement (otherwise more complex logic and several ON-GOSUB statements would be required). Therefore, the subroutines are near the beginning of the program, and the program starts with line 2 and increments by 2. To type in this program using the automatic numbering feature, use NUM 2,2.

## II BASIC String-Handling <br> Reading Practice uses several string functions. It reads the letters from

the DATA statements into $\mathrm{X} \$$ for the word ending and $B \$$ for the beginning letters. W $\$$ holds the word to be printed and read. LEN $(W \$)$ returns the length of the word (or word ending). Lines 170-178 contain a FOR-NEXT loop that executes for each letter of the word. SEG\$ gets one character at a time from the word, and ASC returns the ASCII value of that letter. In TI BASIC, the ampersand symbol (\&) is used to combine strings. (See "The Beginner's Page," June 1986.)

Line 194 combines the beginning letter $\mathrm{B} \$$ with the word ending $X \$$ to form the word $\mathrm{W} \$$. Line 186 adds a period to the word to change its inflection for the speech synthesizer. You may prefer to simply use W\$.

Versions of BASIC on other computers generally use the string functions RIGHT\$, LEFT\$, and MID\$ for extracting sections of strings. The equivalent in TI BASIC is SEG\$. SEG\$(W\$,A,B) looks at the string $W \$$, starts with character number $A$, and returns $B$ number of characters. For example, let's assume that W\$="RICHARD". The Microsoft BASIC statement LEFT\$(W\$,4) is translated into TI BASIC as SEG $\$(W \$, 1,4)$, which yields RICH. The statement RIGHT $(W \$, 4)$ is translated as SEG\$(W\$,LEN(W\$)-4+1,4), which yields HARD. And the statement MID\$(W\$,3,2) is translated as SEG\$(W\$,3,2), which yields CH. (See "The Beginner's Page," April 1986.)

In the Reading Practice program, $\operatorname{SEG} \$(W \$, P, 1)$ is in a loop where $P$ starts at 1 and goes to L , which is the number of characters in the word. This function, then, gets one letter at a time, in order, from the word. The variable A is the ASCII value of that character minus 64 to yield numbers from 1
to 26 for the relative letter．Line 174 then uses ON－GOSUB to go to the proper subroutine to draw the cor－ responding lowercase letter．

If you want to save typing ef－ fort，you may get a copy of this program by sending a blank cas－ sette or disk，a stamped，self－ad－ dressed mailer，and $\$ 3$ to：
C．Regena

## Programming In Modula-2

There are a plethora of programming languages for the Amiga, giving programmers and developers a wide choice of programming styles and systems. There are two versions of BASIC (MetaComCo's ABasiC and Microsoft's Amiga BASIC), two C compilers (Manx Aztec C and Lattice C), a macro assembler/editor, two versions of Pascal, and even an implementation of LISP. Numerous programming tools, such as editors and debuggers, are also available.

A relative newcomer to the scene, TDI Modula-2, is now getting some attention. Some programmers consider it easier to learn and use than C -since it shares many of the high-level aspects of Pascal-while still retaining a ma-chine-level interface for maximum efficiency.

Modula-2 is a descendent of the language Modula, which in turn is a descendent of Pascal. Nicklaus Wirth, the inventor of Pascal, designed Modula from the roots of Pascal, but purposely kept it very simple so that it could be used with very small computers-primarily for controlling hardware devices such as robot arms. The original Modula had little application outside a very specialized world, so Wirth put back most of the features of Pascal to create Modula-2. TDI has worked directly with Wirth to implement versions of Modula-2 for the Amiga and Atari ST.

## Software Chips

The concept of Modula-2 is echoed in its name. It is a language designed specifically for the techniques of modular programming, just as Pascal was designed to make structured programming convenient and elegant. Modular program-ming-the art of breaking a large, complex problem into small, independent tasks-is at the heart of all
programming, but Modula-2 tries to bring to software the modularity inherent in computer hardware, based on off-the-shelf chips and components. With "software chips," Wirth envisioned, software technology could advance apace with the remarkable speed of hardware evolution.

If software chips are possible, they have to be based on program modules that can be truly independent, hence, individually testable. You can compile a module without having to recompile the entire program. A module, once developed, becomes a "black box" routine that accepts input and/or provides output. You no longer need to know how this module works internally to use it-you just plug it in and go. Writing a program becomes a task of putting together these building blocks in the right way without ever needing to reinvent the wheel. Why solve a problem when someone else has already found the solution?

Modula-2 comes with a standard library containing modules for input/output, math routines, and access to special machine features. You use only the routines you're interested in, and only these routines (and the underlying routines they are based on) need to be included in your compiled code. This lets you control the size of your final program.

You can easily add your own library modules. First, you write the definition module, which simply contains the procedure headers that specify the inputs and outputs of a module. The definition module primarily specifies the names of these procedures. It compiles to a symbol file for use by the compiler. The implementation module contains the actual code of the module. You compile the definition module sep-
arately from the implementation module.

You can change and recompile the implementation module without changing the definition module, as long as your procedure headings remain the same. When you're referencing library modules, the compiler can check the compact, compiled symbol file rather than the full-length definition module, speeding up compilation. After compilation, a linker combines your main program with the compiled implementation modules to create the final executable program.

## Reminiscent Of Pascal

One of the best ways to learn about a language is to study an example program. The program accompanying this column is written to demonstrate some of the features of Modula-2 without getting bogged down in tricky algorithms. It's a simple guess-my-number game. The RandomNumbers module thinks of a number from 1 to 100 . The program then gives you ten tries to guess the number, helping out with hints. If you guess too high, the program recommends that you try a smaller number. If you guess too low, you should try a higher number.

Here's how the program works. The first line declares the name of the module. Next, the IMPORT statements specify which external library calls we'll be using. Then we declare the variables. We define the procedure SkipEOL, used to strip away the rest of a line after getting a single-character response. The main loop follows, enclosed by the keywords BEGIN and END. (All Modula-2 keywords must be typed in uppercase, which can be annoying.)

Most of the program looks very much like Pascal, especially the use
of $:=$ for assignments and the required semicolon at the end of each logical line. Also, you won't find GOTO anywhere in this or any Modula-2 program. Instead, you can control looping and program execution with statements like LOOP-EXIT-END, WHILE-END, REPEAT-UNTIL, and IF-THEN-ELSE-END.

You might be interested to know that this program compiles in 35 seconds when the source code is stored in the RAM disk; it takes 37 seconds to compile when the source code is stored on a floppy disk. Linking takes 45 seconds from the RAM disk, and just one minute from a floppy disk. This is quite a bit faster than Lattice $C$ and compares well with Aztec C.

There's much more to Modula2 than this discussion can encompass. The language even permits procedures to run as multitasking programs. Our example doesn't show how easily Modula-2 can take advantage of the Amiga operating system-even a small program would be too large to demonstrate here-but the interface is similar to C's, using Pascal-style RECORDs instead of $C$ structures. It's possible to develop modules that support the Amiga operating system on a higher level, using calls like Screen $(320,200,5)$ to open a custom screen as opposed to filling• in the blanks of a NewScreen structure, opening the Intuition library, and calling OpenScreen( ). Some highlevel modules are included in the library. When these modules are developed and shared between Modula-2 programmers, Amiga programming in Modula-2 can seem almost as easy as in BASIC, but with every advantage of a modern compiled language.

Technology marches on: The price of a hard disk drive-a $\$ 2,000$ luxury just a few years ago-has fallen to a point where it's becoming affordable for home-based computers. Mail-order houses are offering internal hard disks for less than $\$ 400$, and prices of hard disk cards are coming down as well. If you're thinking about upgrading your IBM PC with one of these super storage devices, here are some points to consider.

Hard disk, fixed disk, and Winchester disk are all names for the same thing-a device with a rigid magnetic disk permanently sealed in a box. Because it's sealed from airborne contaminants and has a hard rather than a flexible surface, it can record larger amounts of data than a floppy disk, and the data can be read or written much faster. The smallest hard disks commonly in use store 10 megabytes of datathat's 10,240 kilobytes, or $10,485,760$ characters. In comparison, a standard IBM floppy disk stores only 360 kilobytes- 368,640 characters. Hard disks are available for the PC with capacities of 20,50 , and even 100 megabytes, although a home user isn't likely to need more than 10 megabytes.

Hard disks come in two forms: the internal type that fits into one of the spaces once occupied by a floppy disk drive (half-height or fullheight), and a newer configuration called a hard disk card that squeezes the disk onto a printed circuit board which plugs into one of the PC's expansion slots.

## Can You Spare A Slot?

Every hard disk must have a hard disk controller. An ordinary internal hard disk requires a separate controller board connected via cables to the drive. One advantage of the hard disk cards is that both the disk and the controller are a single compact unit. Either way, one ex-
pansion slot is used. But there is an alternative for internal models. For about $\$ 50$ extra, you can order a controller that runs existing floppy disk drives as well as the hard drive. This allows you to remove (and scrap) your floppy disk controller board and free up one expansion slot. None of the hard disk cards introduced so far can control floppy disk drives.

Another factor to consider is power consumption. Hard disk cards are designed to work with the 63 -watt power supply found in the IBM PC; many of the internal hard disks were designed for the PC-XT, which has a larger power supply. Frankly, if your PC is already brimming with boards-parallel, serial, color/graphics, and game ports as well as memory expansion-you should strongly consider replacing the old power supply no matter which type of hard disk you install. The operation is as simple and safe as removing some screws and unplugging some wires. A new 135watt power supply can be purchased for as low as $\$ 90$.

Of course, speed and reliability are prime considerations when investing in a hard disk. Although reliability is difficult to measure without an industry-wide mean-time-between-failure test, there are some things you can check. An oxide coating on the disk surface is more stable and thus more reliable than plated or sputtered media. The type of actuator that moves the read/write heads across the surface of the platter not only affects speed, but also influences accuracy. A voice-coil actuator is faster and more reliable (and more expensive) than the more common steppermotor actuator. Therefore, look for a hard disk with an oxide coating and voice-coil actuator.

Fast, Faster, Fastest
Speed varies greatly depending on
the make and model. Consider the results of a test which measures a mixture of 1,000 sequential and random accesses-a test that is typical of how real computer programs use a hard disk. The times range from 12 milliseconds for a high-performance internal drive like Core International's AT line, to more then 100 milliseconds for some of the inexpensive hard disk cards. A hard disk for home usewhere you don't need top per-formance-should have a sequential/random access time in the 30to 60 -millisecond range.

Cost is usually a major consideration when selecting a hard disk for home use. Hard disk cards cost as little as $\$ 550$ for a 10 -megabyte unit to as much as $\$ 1,200$ for 20 megabytes. Internal 20-megabyte drives, including the controller board, are generally in the \$400-\$600 range; 10 -megabyte models cost about $\$ 100$ less. The best advice here is not to choose a disk by cost alone. Consider all the factors.

My own PC has a 20 -megabyte internal Seagate drive, a new 135watt power supply, and a controller that also runs two half-height floppy drives. It cost about $\$ 650$ and took two hours to install. An alternative I'd be comfortable with is Plus Development's 10 -megabyte Hardcard; it's designed for those who want a quick, simple installation and who don't want to fool with a new power supply. The Hardcard, at about $\$ 900$, is a wellengineered solution to upgrading your computer's mass storage capabilities.

One final caveat: Whether you spend ten minutes or two hours installing the hardware, plan to spend lots more time learning to use the DOS commands that are necessary to manage files on a hard disk.

# 1. Machine Language Entry Program For Commodore 64 

Ottis Cowper. Technical Editor
"MLX" is a labor-saving utility that allows will help you enter machine language program listings without error. MLX is required to enter all Commodore 64 machine language programs published in COMPUTE!.

Type in and save some copies of MLX (you'll want to use it to enter future ML programs from COMPUTE!, COMPUTE!'s GAZETTE, and COMPUTE! books). When you're ready to enter an ML program, load and run MLX. You'll be asked for a starting address and an ending address. These addresses should appear in the article accompanying the MLX-format program listing you're typing.

If you're unfamiliar with machine language, the addresses (and all other values you enter in MLX) may appear strange. Instead of the usual decimal numbers you're accustomed to, these numbers are in hexadecimal-a base 16 numbering system commonly used by ML programmers. Hexadecimal-hex for short-includes the numerals 0-9 and the letters A-F. But don't worryeven if you know nothing about ML or hex, you should have no trouble using MLX.

After you enter the starting and ending addresses, you'll be offered the option of clearing the workspace. The data you enter with MLX is kept in a special reserved area of memory; clearing this workspace fills the reserved area with zeros, which makes it easier to find where you left off typing if you enter the listing in several sessions. Choose this option if you're starting to enter a new listing. If you're continuing a listing that's partially typed from a previous session, there's no point in clearing the workspace, since the data you load in will fill the area with whatever values were in workspace memory at the time of the last Save.

At this point, functions menu will appear. If you're just starting to type in a program, pick the first option, ENTER DATA, by pressing the E key. You'll be asked for an address; type the four-digit number at the start of the first line of the program listing. If you've already typed in part of a program, be sure to load the partially completed program before you resume entry, then choose the ENTER DATA option and type the line number where you left off typing at the end of the previous session. In any
case, make sure the address you enter corresponds to the address of a line in the listing. Otherwise, you'll be unable to enter the data correctly. If you pressed E by mistake, you can return to the command menu by pressing RETURN alone when asked for the address. (You can get back to the menu from most options by pressing RETURN with no other input.)

## Entering A Listing

Once you're in Enter mode, MLX prints the address for each program line for you. You then type in all nine numbers on that line, beginning with the first two-digit number after the colon (:). Each line represents eight data bytes and a checksum. Although an MLXformat listing appears similar to the "hex dump" listings from a machine language monitor program, the extra checksum number on the end allows MLX to check your typing.

When you enter a line, MLX recalculates the checksum from the eight bytes and the address and compares this value to the number from the ninth column. If the values match, you'll hear a bell tone, the data will be added to the workspace area, and the prompt for the next line of data will appear. But if MLX detects a typing error, you'll hear a low buzz and see an error message. The line will then be redisplayed for editing.

## Invalid Characters Banned

Only a few keys are active while you're entering data, so you may have to unlearn some habits. You do not type spaces between the columns; MLX automatically inserts these for you. You do not press RETURN after typing the last number in a line; MLX automatically enters and checks the line after you type the last digit.

Only the numerals $0-9$ and the letters A-F can be typed in. If you press any other key (with some exceptions noted below), you'll hear a warning buzz. MLX checks for transposed characters. If you're supposed to type in A0 and instead enter OA, MLX will catch your mistake. There is one error that can slip past MLX: Because of the checksum formula used, MLX won't notice if you accidentally type FF in place of 00 , and vice versa. And there's a very slim chance that you could garble a line and still end up with a combination of characters that adds up to the
proper checksum. However, these mistakes should not occur if you take reasonable care while entering data.

## Editing Features

To correct typing mistakes before finishing a line, use the INST/DEL key to delete the character to the left of the cursor. (The cursor-left key also deletes.) If you mess up a line really badly, press CLR/HOME to start the line over. The RETURN key is also active, but only before any data is typed on a line. Pressing RETURN at this point returns you to the command menu. After you type a character of data, MLX disables RETURN until the cursor returns to the start of a line. Remember, you can press CLR/HOME to quickly get to a line number prompt.

More editing features are available when correcting lines in which MLX has detected an error. To make corrections in a line that MLX has redisplayed for editing, compare the line on the screen with the one printed in the listing, then move the cursor to the mistake and type the correct key. The cursor left and right keys provide the normal cursor controls. (The INST/ DEL key now works as an alternative cursor-left key.) You cannot move left beyond the first character in the line. If you try to move beyond the rightmost character, you'll reenter the line. During editing, RETURN is active; pressing it tells MLX to recheck the line. You can press the CLR/HOME key to clear the entire line if you want to start from scratch, or if you want to get to a line number prompt to use RETURN to get back to the menu.

## Display Data

The second menu choice, DISPLAY DATA, examines memory and shows the contents in the same format as the program listing (including the checksum). When you press D, MLX asks you for a starting address. Be sure that the starting address you give corresponds to a line number in the listing. Otherwise, the checksum display will be meaningless. MLX displays program lines until it reaches the end of the program, at which point the menu is redisplayed. You can pause the display by pressing the space bar. (MLX finishes printing the current line before halting.) Press space again to restart the display. To break out of the display and
get back to the menu before the ending address is reached, press RETURN.

## Other Menu Options

Two more menu selections let you save programs and load them back into the computer. These are SAVE FILE and LOAD FILE; their operation is quite straightforward. When you press S or L, MLX asks you for the filename. You'll then be asked to press either D or T to select disk or tape.

You'll notice the disk drive starting and stopping several times during a load or save. Don't panic; this is normal behavior. MLX opens and reads from or writes to the file instead of using the usual LOAD and SAVE commands. Disk users should also note that the drive prefix 0 : is automatically added to the filename (line 750), so this should not be included when entering the name. This also precludes the use of @ for Save-with-Replace, so remember to give each version you save a different name.

Remember that MLX saves the entire workspace area from the starting address to the ending address, so the save or load may take longer than you might expect if you've entered only a small amount of data from a long listing. When saving a partially completed listing, make sure to note the address where you stopped typing so you'll know where to resume entry when you reload.

MLX reports the standard disk or tape error messages if any problems are detected during the save or load. (Tape users should bear in mind that Commodore computers are never able to detect errors during a save to tape.) MLX also has three special load error messages: INCORRECT STARTING ADDRESS, which means the file you're trying to load does not have the starting address you specified when you ran MLX; LOAD ENDED AT address, which means the file you're trying to load ends before the ending address you specified when you started MLX; and TRUNCATED AT ENDING ADDRESS, which means the file you're trying to load extends beyond the ending address you specified when you started MLX. If you see one of these messages and feel certain that you've loaded the right file, exit and rerun MLX, being careful to enter the correct starting and ending addresses.

The QUIT menu option has the obvious effect-it stops MLX and enters BASIC. The RUN/STOP key is disabled, so the $Q$ option lets you exit the program without turning off the computer. (Of course, RUN/STOP-RESTORE also gets you out.) You'll be asked for verification; press $Y$ to exit to BASIC, or any other key to return to the
menu. After quitting, you can type RUN again and reenter MLX without losing your data, as long as you don't use the clear workspace option.

## The Finished Product

When you've finished typing all the data for an ML program and saved your work, you're ready to see the results. The instructions for loading and using the finished product vary from program to program. Some ML programs are designed to be loaded and run like BASIC programs, so all you need to type is LOAD "filename", 8 for disk or LOAD "filename" for tape, and then RUN. Such programs will usually have a starting address of 0801. Other programs must be reloaded to specific addresses with a command such as LOAD "filename", 8,1 for disk or LOAD "filename" $, 1,1$ for tape, then started with a SYS to a particular memory address. The most common starting address for such programs is 49152 , which corresponds to MLX address C000. In either case, you should always refer to the article which accompanies the ML listing for information on loading and running the program.

## An Ounce Of Prevention

By the time you finish typing in the data for a long ML program, you may have several hours invested in the project. Don't take chances-use our "Automatic Proofreader" to type MLX, and then test your copy thoroughly before first using it to enter any significant amount of data. Make sure all the menu options work as they should. Enter fragments of the program starting at several different addresses, then use the Display option to verify that the data has been entered correctly. And be sure to test the Save and Load options several times to ensure that you can recall your work from disk or tape. Don't let a simple typing error in MLX cost you several nights of hard work.

## MLX

For instructions on entering this listing, please refer to "COMPUTEI's Guide to Typing in
Programs" in this issue of COMPUTEI.

## New Products From Batteries Included

An extensive array of new software programs for Apple, Atari, Commodore, and IBM computers has been announced by Batteries Included. The list includes the following:
$I^{*} S$ Talk is a full-featured GEMbased telecommunications program for the Atari ST and the IBM PC. The program is part of the company's Integral Solutions line of GEM-based products. I*S Talk features a built-in 50,000-word spelling checker, three levels of automation functions, keystroke macros, and an unlimited capture buffer including $X$-modem file transfers. Other features include Replay, and a unique session recorder. A custom keyboard interface is built in, allowing you to use the mouse or function keys and keyboard.

Suggested retail prices are $\$ 79.95$ for the ST version and $\$ 99.95$ for the IBM version.

The popular HomePak three-in-one word processor, database manager, and telecommunications package should be available by the time you read this in versions for the Apple Macintosh, the Atari ST, and the Commodore 128 computers. HomePak sells for $\$ 49.95$, and is already available for the Commodore 64, Apple II, IBM PC/PCjr, and Atari XL/XE computers.

The PaperClip II word processor for the Commodore 128 is designed to take advantage of the 128's memory, speed, and power. The program includes a built-in telecommunications module for use with online services, a 20,000-word spell checker, macro capability, multiple columns, reverse video scroll, word wrap, chaptering, and an expanded maximum document size. PaperClip II, priced at $\$ 79.95$, is completely compatible with PaperClip text files on the Commodore 64. Also new (or planned for release soon) are PaperClip With SpellPack for the Atari 130XE (\$59.95); PaperClip for the Apple II, II + , IIc, and IIe computers (\$59.95); and I*S PaperClip Elite for the IBM PC and compatibles (\$129.95), Atari ST (\$79.95), and Commodore Amiga (\$129.95). PaperClip Elite includes all of the earlier PaperClip features, plus ad-
vanced functions such as a real-time spelling checker, idea processing, independent linked windows, integrated text and graphics, and other capabilities.
$I^{*} S$ Degas Elite, an upgraded version of the original Degas graphics and design program for the Atari ST, will be available soon for the IBM PC and compatibles, Amiga, and ST. The program includes everything in the original, plus features like FLIP, SCALE, ROTATE, and the ability to cut and paste between pictures on multiple work screens. $D E$ GAS Elite files can also be integrated with PaperClip Elite text files, and all Degas Elite files are compatible with the original Degas.

Batteries Included will also be marketing The Isgur Portfolio System (IPS) for the IBM PC (\$249.95), the Atari ST (\$199.95), the Amiga (\$249.95), and the Apple Macintosh (\$249.95). This is an investment management program designed by Lee Isgur, Wall Street analyst and first vice president of Paine Webber in New York. IPS lets you update your portfolios automatically from online services, and provides a variety of analytical tools for more profitable decision making.

BTS The Spreadsheet is a $\$ 69.95$ spreadsheet for the Macintosh, Atari ST, and Amiga that includes key math, statistical, and financial functions, logical operators, formatting enhancements, and other features. Maximum worksheet size is 1000 rows by 1000 columns. Desk accessory version is included on the same Macintosh and ST disks.

TimeLink is an electronic diary program for planning and record-keeping, available for the Macintosh and Atari ST for $\$ 49.95$ each. $I^{*}$ S Time And Billing is a professional office administration program planned for the fourth quarter of 1986 for IBM and Atari ST computers. $I^{*} S$ Consultant, also planned for the fourth quarter, is an enhanced Atari ST version of the original Consultant database. The new program will use the GEM interface and contain additional features. B/GRAPH Elite (a fourth quarter release) is a $\$ 69.95$ graphics/charting and statistical analysis package for the Atari ST.

Soon to be available is Thunder, a
$\$ 39.95$ writer's accessory that can be called for use from within any GEMbased Atari ST application. Features include a 50,000 -word spelling checker with three different error-catching modes and an immediate word replacement capability. An Abbreviation function will even supply you with the remainder of the word, or words, you want when you type in just the first few letters. And a built-in report analyzer gives you details on everything from word count to the document's relative readability.

Batteries Included, 30 Mural St., Richmond Hill, Ontario, Canada L4B 1B5. Circle Reader Service Number 200.

## Abacus Software, Book

Abacus Software has introduced several Atari ST software applications packages, each priced at $\$ 39.95$. ST TextPro is a word processor that features multicolumn output, automatic indexing and table of contents, scrolling, definable function keys, sideways output (to Epson printers), and printer drivers for other printers. The program allows fullscreen editing with either mouse or keyboard commands.

ST Text Designer is a pagemaking package for creating layouts from word processing files. The program reads text files from ST TextPro and other ASCII word processors, and allows block operations. Graphics can be merged into the layout, and borders and lines can be added. Output is to Epson-compatible printers.

ST DataPro is a data management package that lets you input data through screen templates. Record length is unlimited, with a maximum of 64,000 records available. The package also supports a RAM disk as well as a floppy disk. ST Forth/MT is a multitasking implementation of the Forth programming language, based on Forth 83. The program supports 32 -bit arithmetic, has more than 1500 commands, and includes a full-screen editor, Forth macro assembler, and monitor and disk monitor.

Abacus is also announcing $S T$ PaintPro, a drawing program, and $S T$ AssemPro, an assembly language development package.

For the Commodore 128 computer, Abacus recently released another volume in its Commodore 128 Reference Library. The $\$ 19.95$ title is Commodore 1571 Internals.

Abacus Software, P.O. Box 7211, Grand Rapids, MI 49510. Circle Reader Service Number 201.

## 64 Software From Firebird

Firebird has released several new software packages for the Commodore 64 and 128.

The Music System is a comprehensive music development package that includes full sonic tailoring of the computer's SID chip, multi-voicing, mono or polyphonic modes, editing, recording, and storage and playback of sound settings and compositions.

There is an advanced version of The Music System which includes the features of the standard version and adds MIDI capabilities (compatible with either S.I.E.L. or Passport Designs MIDI interfaces). The advanced version enables the user to link and edit sequences, control six MIDI tracks or devices simultaneously, print sheet music, and also permits automatic transpositions and automatic tempo conforming and correcting. You can upgrade the standard version to the advanced version at a nominal cost.

Gerry The Germ and Microcosm are the newest in the Firebird Super Silver Disk Series. Both games feature music, sound effects, graphics, and animation. Gerry The Germ is a journey through the human body with Gerry as the guide. In Microcosm, the player must defend the agricultural cargo of a crippled interstellar freightliner against a hoard of mutant insects. The games are on one flippy disk and require either joystick or keyboard control.

The standard version of The Music System has a suggested retail price of $\$ 39.95$ and the advanced version is $\$ 79.95$. The Gerry The Germ/Microcosm Super Silver Disk Series package retails for \$19.95.

Firebird, P.O. Box 49, Ramsey, NJ 07446.

Circle Reader Service Number 202.

## New Games From Intellicreations

Intellicreations (formerly Datasoft) has announced the release of three new games.

The Never Ending Story is an adventure/fantasy game based on the book and film of the same name. Cast as the hero, Atreyu, and aided by Falkor, the luck dragon, you face the trials and terrors of the ever-consuming "nothing" in an illustrated and imaginative
computer adventure. The Never Ending Story is now available as a flippy for Commodore and Atari 8-bit machines (Commodore version on one side, Atari on the flip side), and for the Apple II computers. All versions retail for $\$ 29.95$.

Mind Pursuit is a test of intelligence, knowledge, and trivia with three levels of difficulty. At the simplest level are true/false questions; next are multiple choice; and finally, and most difficult, are fill-in-the-blanks. The game is designed with questions for both adults and children, and has three difficulty levels, so the whole family can play together. Music and graphics clues are also used for variety, and provide further challenges to the game play. Additional game disks are available. Commodore and Apple versions retail for \$29.95; add-on disks are \$14.95.

221B Baker Street is the address of fictional super-sleuth Sherlock Holmes. In the game 221B Baker Street, you start at that address and travel through the streets and alleys of London, gathering clues that will lead to the solution of some of the most intriguing cases ever faced by Holmes and his assistant, Dr. Watson. The initial game will include 30 different cases; two additional game disks will be available later, each containing 30 more cases. Atari, Commodore, and Apple versions retail for $\$ 29.95$, with follow-up disks costing \$14.95 each.

Intellicreations, 19808 Nordhoff Pl., Chatsworth, CA 91311.

Circle Reader Service Number 203.

## 128 Telecommunications And 64 Graphics

Progressive Peripherals \& Software has announced two new products for the Commodore 64 and 128.

For the Commodore 128, BobsTerm Pro-128 is a menu-driven communications package that lets you edit files while it reads, writes, uploads, and downloads to any disk type (including $\mathrm{CP} / \mathrm{M})$. The package supports VT-100 and VT-52 80 ADM-31 (CP/M type) terminal emulation, and includes a fullscreen text editor, on-screen status display, remote mode, macro and answerback string functions, and a manual. The program is compatible with most modems and works with high speed 1571 disk drives, the SFD-1001, and Commodore and MSD dual drives.

With Picasso's Revenge, you can draw circles, squares, triangles, and many other geometric figures with the Commodore 64. This graphics package has 35 predefined textures, five-level focus, and a ZOOM command that magnifies the screen area eight times. The program supports high-resolution
drawings made with Koala, Suncom, Paint Majic, and other commonly used graphics programs. It's compatible with most dot-matrix printers and prints in nine shades of gray. The Picasso's Revenge package includes a free light pen and a user's manual.

BobsTerm Pro-128 retails for \$79.95 and Picasso's Revenge for $\$ 59.95$.

Progressive Peripherals \& Software, 464 Kalamath St., Denver, CO 80204.
Circle Reader Service Number 204.

## Amiga Fonts

Classic Concepts FUTUREWARE has announced new type fonts for Amiga users who need larger fonts for video titling, graphics, desktop publishing, and other applications. FUTUREWARE FONTS can be used to mix titles with video images (with Genlock) and are more clearly legible in high resolution mode than fonts with the Workbench disk. The fonts are compatible with Notepad, Deluxe Paint, Aegis Images, and other common Amiga software

Each package includes a disk utility installation program, 13 new fonts, and a font reference booklet.

Retail price is $\$ 14.95$, plus $\$ 1$ shipping and handling.

FUTUREWARE FONTS, P.O. Box 94276, Richmond, B.C., Canada V6Y $2 A 6$. Circle Reader Service Number 205.

## Apple II Science Software

Science Toolkit-Master Module lets you perform real experiments with your Apple computer and two sensory probes. Each package contains an interface box, light probe, temperature probe, light probe stand, light guard, two lab notebook labels, and a 125page User's Manual \& Experiment Guide that details how to use the probes and the on-screen instruments-thermometer, light meter, timer, and strip chart.

Science Toolkit-Master Module is for the Apple IIe and IIc with 64 K memory. Printer is optional and the interface box is included. Users should be 12 years old and up.

There is a school version which includes a teacher's guide in addition to the material provided in the standard package. For use in grades 4-12.

The standard version retails for $\$ 69.95$ and the school version retails for $\$ 89.95$. Anyone with the standard version can buy the teacher's guide separately for $\$ 20$.

Brøderbund Software, Inc., 17 Paul Dr., San Rafael, CA 94903-2101.
Circle Reader Service Number 206.

## From the publishers of COMPUTE!

## July 1986 COMPUTE! Disk

All the exciting programs from the past three issues of COMPUTE! are on timesaving, error-free floppy disks that are ready to load on your IBM PC and PCjr or Commodore 64 and 128. The July 1986 COMPUTE!
Disks contain the entertaining and useful Commodore or IBM programs from the May, June, and July 1986 issues of COMPUTE!.

The July 1986 COMPUTE! Disk costs $\$ 12.95$ plus $\$ 2.00$ shipping and handling and is available only from COMPUTE! Publications. Please specify whether you need a Commodore or IBM disk.

For added savings and convenience, you may also subscribe to the COMPUTE! Disk. At a cost of only $\$ 39.95$ a year (a $\$ 12.00$ savings), you'll receive four disks, one every three months. Each disk will contain all the programs for your machine from the previous three issues of COMPUTE!.

This is an excellent way to build your software library while you enjoy the quality programs from COMPUTE!.

Disks and subscriptions are available for Apple, Atari, Commodore 64 and 128, and IBM personal computers. Call for details.

For more information or to order the July 1986 COMPUTE! Disk, call toll free 1-800-346-6767 (in NY 212-265-8360) or write COMPUTE! Disk, P.O. Box 5038, F.D.R. Station, New York, NY 10150.

## Atari COMPUTE! DISK

The first quarterly COMPUTE! DISK for Atari, containing the programs from the January-March 1986 issues, has caused some confusion among those who received it. First, the disk does not contain a disk operating system (DOS) and therefore cannot be used to start up the computer. As the disk label instructs, you must boot your system using your own DOS disk, make sure you are in BASIC, then put the COMPUTE! DISK in the drive and type RUN "D:MENU". The disk is in Atari DOS 2.0 S format, which can also be read by Atari DOS 2.5 and most third-party operating systems such as DOS XL and OS/A + . Atari DOS 3.0 has an option to convert DOS 2.0 files to 3.0 format. However, if you're still using DOS 3.0 you should seriously consider switching to DOS 2.5 (despite the confusing numbering, version 2.5 is newer than 3.0). DOS 2.5 is available free from many Atari dealers and user groups. It is not possible to write DOS files to the COMPUTE! DISK because it is write protected and because there isn't enough room on the disk for any more files.

Note, however, that while the COMPUTE! DISK is write protected, it is not copy protected. When you receive the disk, you should first make a backup copy. (With Atari DOS 2.0 or 2.5 , use option J-Duplicate Disk). Programs such as SpeedScript and SpeedCalc will be more useful if copied to a disk that contains the DOS system files. (With Atari DOS 2.0 or 2.5, use option O-Duplicate File).

There is one program on the January-March Atari disk that cannot be used as-is with Atari DOS. "High Rise" was designed to be a boot disk file if typed in from the magazine using MLX. The verison on the disk was intended to be executed as a binary file, but we failed
to explain that and also failed to put the program on the disk in the proper format for the Atari DOS L (Load Binary File) option. The problem is easy to correct, though. Copy the HIRISE.FEB program from the COMPUTE! DISK to another disk (preferably one that contains DOS) using the O option in Atari DOS $2.0 / 2.5$, then enter and run the following one-line program:

```
1\varnothing OPEN #1,9,\emptyset,"D:HIRISE.
    FEB":PUT #1,224:PUT #1
    ,2:PUT #1,225:PUT #1,2
    :PUT #1,ø:PUT #1,48:CL
    OSE #1
```

This fixes the file so the game can be played by going to the Atari DOS 2.0/2.5 menu and using the L option. Specify HIRISE.FEB as the file to load; it begins running automatically after loading. You could also use the DOS menu's E option to rename the fixed file to AUTORUN.SYS. In that case, the program will load and run automatically when the disk is booted. If you're using OS/A + DOS or DOS XL, you can run High Rise simply by typing HIRISE.FEB at a DOS D1: prompt, so the above correction is not necessary.

The January-March Atari disk does not contain the programs "MLX" and "Automatic Proofreader" because the disk was too full for them to be included. They appear on the April-June Atari disk and should be on all future Atari disks when space allows. We know of no special problems with any of the programs on the April-June disk.

## 64 Autobooter

The automatic loading technique used in this program from the May issue (p. 92) should work fine for the first program autobooted after the computer is turned on. However, when autobooting more than one program in a session, the routine
may fail if a later autoboot attempts to load a program shorter than the one previously autobooted. To correct this, change the following lines:

GA 140 IF $\mathrm{S}<>51988$ THEN PRINT: PRINT"MISTYPED DATA": EN D
DF 2 Øø IF $\mathrm{B}>7936$ THEN PRINT CH R\$(18); STR $(B-7936) "$ \{2 SPACES\}BYTE OVERFLOW ": GOTO 160
CG 550 DATA $57,224,32,176,12,1$ 89,16,255
BE $71 \varnothing$ DATA $1 \varnothing 4,2 ø 8,11,32,51,1$ 65,162,54
AS 720 DATA $160,2,134,122,132$, 123,162,31
EF $73 \varnothing$ DATA $169, \varnothing, 157,16,245,2$ ø2,16,25ø
RM $74 \varnothing$ DATA $169,13,76,210,255$, $138, \varnothing, \varnothing$

## Minding IBM Memory

Line 100 in Program 3 (p. 86) of this memory management utility in the June issue contains an error that prevents the deallocation routine from properly releasing allocated blocks of memory. The \&h85 in that line should be \&h 8 b , as shown in the assembly listing for the deallocation routine (Program 2).

## Using PALETTE USING

In Program 2 from this article in the May issue (p. 71), the AS $\$=$ " N " at the end of line 80 should instead be AN $\$=$ " $\mathrm{N} "$.

## Commodore Loading and Linking, Part 4

In the example program in the lowerright corner of page 75 in the June issue, omit the question mark in the value 128 in line 140 . The question mark was caused by a printer malfunction.

# COMPUTEI's Guide To Typing In Programs 

Computers are precise-type the program exactly as listed, including necessary punctuation and symbols, except for special characters noted below. We have provided a special listing convention as well as a program to check your typing- "The Automatic Proofreader."

Programs for the IBM, TI-99/4A, and Atari ST models should be typed exactly as listed; no special characters are used. Programs for Commodore, Apple, and Atari $400 / 800 /$ XL/XE computers may contain some hard-toread special characters, so we have a listing system that indicates these control characters. You will find these Commodore and Atari characters in curly braces; do not type the braces. For example, $\{$ CLEAR $\}$ or $\{$ CLR $\}$ instructs you to insert the symbol which clears the screen on the Atari or Commodore machines. A complete list of these symbols is shown in the tables below. For Commodore, Apple, and Atari, a single symbol by itself within curly braces is usually a control key or graphics key. If you see $\{A\}$, hold down the CONTROL key and press A. This will produce a reverse video character on the Commodore (in quote mode), a graphics character on the Atari, and an invisible control character on the Apple.

Graphics characters entered with the Commodore logo key are enclosed in a special bracket: $[K A>]$. In this case, you would hold down the Commodore logo key as you type A. Our Commodore listings are in uppercase, so shifted symbols are underlined. A graphics heart symbol (SHIFT-S) would be listed as $\underline{S}$. One exception is \{SHIFTSPACE \}. When you see this, hold down SHIFT and press the space bar. If a number precedes a symbol, such as $\{5$ RIGHT $\}$, $\{6 \underline{\mathrm{~S}}\}$, or $\mathrm{K} 8 \mathrm{Q}>$, you would enter five cursor rights, six shifted S's, or eight Commodore-Q's. On the Atari, inverse characters (white on black) should be entered with the inverse video

## Atarl 400/800/XL/XE

key（Atari logo key on $400 / 800$ models）．
Whenever more than two spaces appear in a row，they are listed in a special format．For example，$\{6$ SPACES $\}$ means press the space bar six times．Our Commodore listings never leave a single space at the end of a line， instead moving it to the next printed line as $\{\mathrm{SPACE}\}$ ．

Amiga program listings contain only one special character，the left ar－ row $(\mapsto)$ symbol．This character marks the end of each program line．Wherever you see a left arrow，press RETURN or move the cursor off the line to enter that line into memory．Don＇t try to type in the left arrow symbol；it＇s there only as a marker to indicate where each pro－ gram line ends．

## The Automatic Proofreader

Type in the appropriate program listed below，then save it for future use．The Commodore Proofreader works on the Commodore 128，64，Plus／4，16，and VIC－20．Don＇t omit ary lines，even if they contain unfamiliar commands or you think they don＇t apply to your com－ puter．When you run the program，it installs a machine language program in memory and erases its BASIC portion automatically（so be sure to save sever－ al copies before running the program for the first time）．If you＇re using a Commodore 128，Plus／4 or 16，do not use any GRAPHIC commands while the Proofreader is active．You should disable the Commodore Proofreader before running any other program．To do this，either turn the computer off and on or enter SYS 64738 （for the 64），SYS 65341 （128），SYS 64802 （VIC－20），or SYS 65526 （Plus $/ 4$ or 16）．To reenable the Proofreader，reload the program and run it as usual．Unlike the original VIC／64 Proofreader，this version works the same with disk or tape．

On the Atari，run the Proofreader to activate it（the Proofreader remains active in memory as a machine lan－ guage program）；you must then enter NEW to erase the BASIC loader．Press－ ing SYSTEM RESET deactivates the Atari Proofreader；enter PRINT USR（1536）to reenable it．

The Apple Proofreader erases the BASIC portion of itself after you run it， leaving only the machine language por－ tion in memory．It works with either DOS 3.3 or ProDOS．Disable the Apple Proofreader by pressing CTRL－RESET before running another BASIC program．

The IBM Proofreader is a BASIC program that simulates the IBM BASIC line editor，letting you enter，edit，list， save，and load programs that you type． Type RUN to activate．Be sure to leave Caps Lock on，except when typing low－ ercase characters．

Once the Proofreader is active，try typing in a line．As soon as you press RETURN，either a hexadecimal number （on the Apple）or a pair of letters（on the Commodore，Atari，or IBM）appears． The number or pair of letters is called a checksum．

Compare the value displayed on the screen by the Proofreader with the checksum printed in the program list－ ing in the magazine．The checksum is given to the left of each line number． Just type in the program a line at a time （without the printed checksum），press RETURN or Enter，and compare the checksums．If they match，go on to the next line．If not，check your typing； you＇ve made a mistake．Because of the checksum method used，do not type abbreviations，such as ？for PRINT．On the Atari and Apple Proofreaders， spaces are not counted as part of the checksum，so be sure you type the right number of spaces between quote marks．The Atari Proofreader does not check to see that you＇ve typed the char－ acters in the right order，so if characters are transposed，the checksum still matches the listing．The Commodore Proofreader catches transposition er－ rors and ignores spaces unless they＇re enclosed in quotation marks．The IBM Proofreader detects errors in spacing and transposition．

## IBM Proofreader Commands

Since the IBM Proofreader replaces the computer＇s normal BASIC line editor，it has to include many of the direct－mode IBM BASIC commands．The syntax is identical to IBM BASIC．Commands simulated are LIST，LLIST，NEW， FILES，SAVE，and LOAD．When listing your program，press any key（except Ctrl－Break）to stop the listing．If you enter NEW，the Proofreader prompts you to press $Y$ to be especially sure you mean yes．

Two new commands are BASIC and CHECK．BASIC exits the Proof－ reader back to IBM BASIC，leaving the Proofreader in memory．CHECK works just like LIST，but shows the checksums along with the listing．After you have typed in a program，save it to disk． Then exit the Proofreader with the BASIC command，and load the pro－ gram as usual（this replaces the Proof－ reader in memory）．You can now run the program，but you may want to re－ save it to disk．This will shorten it on disk and make it load faster，but it can no longer be edited with the Proofread－ er．If you want to convert an existing BASIC program to Proofreader format， save it to disk with SAVE＂filename＂， A ．

# Expert Back-up for Atari Users. samancon BACKUP HARDWARE \& SOFTWARE 

# THE 1050 DUPLICATOR: The most powerful diskdrive copy system ever developed for the ATARI. 

# The only Copy system You will ever need. What will it do? 

- The main purpose of the Dupllcator is to copy disksI You will be able to copy just about any disk! The copies you make will run on any Atari drive. The Duplicator need not be present to run your backup copies. The Duplicator is fully automatic. You need only insert source and destination disks. Custom formats will be read and in turn reproduced on the backup copy disk. Our device will reproduce any custom format or heavily copy guarded scheme, bad sectors, double sectors, 19 through 24 sector format will present no problem to the Duplicator.

You will still have single density, density and one half, and double density. When you have a Duplicator installed in a 1050 drive that drive will be turned into true double density. You will have twice the disk storage. Your drive will be compatible with other double density drives as The Rana indus. Percom, etc.

-High speed read \& write. Your disk drive will read and load ll of your software, saving wear and tear on your drive. The 050 drive now reads one sector at a time. This is slow and nefficient. With the duplicator installed you will be able to read eighteen sectors in the time it takes standard. unenhanced drives to read one.

- Included with every Duplicator will be user frlendly disk software. A simple, menu driven program will allow you to copy all of your software. A Duplicator enhanced drive will be a SMART drive. We plan to write many new and exciting programs that can only be run on an enhanced drive, eg. sending a copy-guarded disk over the phone. Since the
drive is now fully programmable future upgrades drive is now fully programmable, future upgrades can be made available to you on disks, should the need arise. No further hardware changes will ever be needed. The Duplicator comes with a full hardware and software guarantee.
- 

Plus $\$ 3.50$ for Shipping \& Handling
Only
Fully Compatible with the XL \& New XE Series.
HARDWARE POWER

## GASY 5 MINUTE INSTAILATION

NO HARM TO YOUR DRIVE OR INCOMPATBBLLIT PROBLEMS CAN ARISE AS A RESULT OF THE INSTALLATION OF OUR DUPLICATOR

## 520 ST Copy Program <br> THE ST DUPLICATOR ${ }^{\text {TM }}$

Our famous 1050 DUPLICATOR has been converted to service the ATARI ${ }^{\text {w }} 520$ ST. It is a software only disc copy system.
You can now back up heavily copy-guarded and protected discs. Presently, we can't find anything the ST DUPLICATOR will not copy. And if new forms of software protection should appear on the market, we will provide software upgrades.

ST DUPLICATOR ${ }^{\text {™ }}$ INCLUDES USER
FRIENDLY SOFTWARE AND INSTRUCTIONS

## DENSITY "DOUBLER"

## 1050

## DOUBLE THE POWER...

 TRIPLE THE SPEED...Get TRUE double density, full compatibility with any DOS. Now store twice as much data on each disk. Read and write up to $3 \times$ faster in single or double density (Whole Track Buffering). Includes ultra-speed software, simple plug-in PC board No soldering or cutting required.

Plus $\$ 3.50$ Shipping Add $7 \%$ Outside U.S.A

## WRITE-RIGHT

This device will allow you to write to side 2 of any disk. Install this box to your ATARI ${ }^{\text {tu }} 1050$ in 5 minutes. Just plug in one cable - no cutting or soldering required. Push a button and a LED will light, allowing you to write to a disk without notching out a hole in the disk. Easy plug-in installation. Instructions included. Fully tested \& assembled.

## THE HACKER'S TREASURE CHEST On Disk

18 Utility Programs on disk. Each program is specifically designed to aid you in backing-up your software collection. You will be able to duplicate disks cartridges and cassettes. Any one program is worth the price of all 18. It has taken us over one year to put together this fine collection on the Hacker's Treasure Chest disk. Some of the programs you will receive are Cartridge Copy, Bootape Maker, Tape to Disk, SectorCopy, The Unprotector, Sector Disassembler, Bad Sector Finder, Modem Program... plus more. All of these programs plus 10 more on this disk. You will also receive a menu that will run basic and binary flies just by typing the number of the program. Any file on any disk will load automatically from this menu. ALL FOR ONLY

"Constantly Working on New Products and Software."

AT LAST! A FULL IMPLEMENTATION of the original ELIZA program is now available to run on your personal computer! Created at MIT in 1966, ELIZA has become the world's most celebrated artificial intelligence demonstration program. ELIZA is a non-directive psychotherapist who analyzes each statement as you type it in and then responds with her own comment or question - and her remarks are often amazingly appropriate!
Designed to run on a large mainframe, ELIZA has never before been Designed to run ona lable to personal computer users except in greatly stripped down versions lacking the sophistication which made the original program so fascinating.
Now, our new personal computer version possessing the FULL power Now, ournew ersoression of the original is being offered at the and range of expressily $\$ 45$. And to let you find out how she does it (or teach her to do more) we have included the complete SOURCE PROGRAM (written in BASIC) at no extra cost.
Order your copy of ELIZA today and you'll never again wonder how to respond when you hear someone say, "Okay, let's see what this computer of yours can actually do!"'
READ WHAT THE EXPERTS SAY ABOUT OUR VERSION OF ELIZA: "Much more than a mere game ... You'll be impressed with ELIZA ...A convincing demonstration of Artificial Intelligence."

## COMPUTEI Classified is a low-cost way to tell over 350,000 microcomputer owners about your product or service.

Rates: $\$ 25$ per line, minimum of four lines. Any or all of the first line set in capital letters at no charge. Add $\$ 15$ per line for boldface words, or $\$ 50$ for the entire ad set in boldface (any number of lines.) Inquire about display rates.
Terms: Prepayment is required. Check, money order, American Express, Visa, or MasterCard is accepted. Make checks payable to COMPUTE! Publications.
Form: Ads are subject to publisher's approval and must be either typed or legibly printed. One line equals 40 letters and spaces between words. Please underline words to be set in boldface.
General Information: Advertisers using post office box numbers in their ads must supply permanent address and telephone numbers. Orders will not be acknowledged. Ad will appear in next available issue after receipt.
Closing: 10th of the third month preceding cover date (e.g., June issue closes March 10th). Send order and remittance to: Harry Blair, Classified Manager, COMPUTE!, P.O. Box 5406, Greensboro, NC 27403. To place an ad by phone, call Harry Blair at (919) 275-9809.
Notice: COMPUTE! Publications cannot be responsible for offers or claims of advertisers, but will attempt to screen out misleading or questionable copy.

## Save Your Copies of COMPUTE!

Protect your back issues of COMPUTE! in durable binders or library cases. Each binder or case is custom-made in flag-blue binding with embossed white lettering. Each holds a year of COMPUTE!. Order several and keep your issues of COMPUTE! neatly organized for quick reference. (These binders make great gifts, too!)

## Flight Simulator II Scenery Disks

## The Challenge of Accomplished Flight

With a realism comparable to (and in some ways even surpassing) $\$ 100,000$ aircraft flight simulators, Flight Simulator II includes full flight instrumentation and avionics, and provides a full-color out-thewindow view. Instruments are arranged in the format standard to modern aircraft. All the radios needed for IFR flight are included. Front, rear, left, right, and diagonal views let you look in any direction. Program features are clearly documented in a 96-page Pilot's Operating Handbook.

For training in proper flight techniques, Flight Simulator II includes another 96 -page instruction manual, compiled by two professional flight instructors with over 8,000 hours flight time and 12,000 hours of aviation teaching experience. You'll learn correct FAArecommended flight procedures, from basic aircraft control through instrument approaches. To reward your accomplishments, the manual even includes a section on aerobatic maneuvers.

Apple and Atari versions will be released soon. Each disk covers a geographical region of the country in detail, and is very reasonably priced.

## The Pure Fun of "World War I Ace"

When you think you're ready, you can test your flying skills with the "World War I Ace" aerial battle game. This game sends you on a bombing run over heavily-defended enemy territory. Six enemy fighters will attempt to engage you in combat as soon as war is declared. Your aircraft can carry five bombs, and your machine guns are loaded with 100 rounds of ammunition.

See Your Dealer. Flight Simulator II is available on disk for the Apple II. Atari XL/XE, and Commodore 64/I28 computers for $\$ 49.95$. Scenery Disks for the C64 and IBM PC (jet or Microsoft Flight Simulator) are \$19.95 each. A complete Western U.S. Scenery six-disk set is also available for $\$ 99.95$. For additional product or ordering information, call (800) 637-4983.

## The Realism and Beauty of Flight

Go sight-seeing over detailed, realistic United States scenery. High-speed graphic drivers provide an animated out-the-window view in either day, dusk, or night flying modes.

Flight Simulator II features over 80 airports in four different scenery areas: New York, Chicago, Seattle, and Los Angeles. Six additional Scenery Disks covering the entire Western half of the United States are now available in IBM and C64/I 28 disk formats.
