COLOR COMPUTER
DISK EDITOR ASSEMBLER WITH ZBUG

CUSTOM MANUFACTURED
IN USA BY RADIO SHACK
A DIVISION OF TANDY CORPORATION

TERMS AND CONDITIONS OF SALE AND LICENSE OF RADIO SHACK COMPUTER EQUIPMENT AND SOFTWARE PURCHASED FROM A RADIO SHACK COMPANY-OWNED COMPUTER CENTER, RETAIL STORE OR FROM A RADIO SHACK FRANCHISEE OR DEALER AT ITS AUTHORIZED LOCATION

LIMITED WARRANTY

I. CUSTOMER OBLIGATIONS

- A. CUSTOMER assumes full responsibility that this Radio Shack computer hardware purchased (the "Equipment"), and any copies of Radio Shack software included with the Equipment or licensed separately (the "Software") meets the specifications, capacity, capabilities, versatility, and other requirements of CUSTOMER.
- B. CUSTOMER assumes full responsibility for the condition and effectiveness of the operating environment in which the Equipment and Software are to function, and for its installation

II. RADIO SHACK LIMITED WARRANTIES AND CONDITIONS OF SALE

- A. For a period of ninety (90) calendar days from the date of the Radio Shack sales document received upon purchase of the Equipment, RADIO SHACK warrants to the original CUSTOMER that the Equipment and the medium upon which the Software is stored is free from manufacturing defects. THIS WARRANTY IS ONLY APPLICABLE TO PURCHASES OF RADIO SHACK EQUIPMENT BY THE ORIGINAL CUSTOMER FROM RADIO SHACK COMPANY-OWNED COMPUTER CENTERS, RETAIL STORES AND FROM RADIO SHACK FRANCHISES AND DEALERS AT ITS AUTHORIZED LOCATION. The warranty is void if the Equipment's case or cabinet has been opened, or if the Equipment or Software has been subjected to improper or abnormal use. If a manufacturing defect is discovered during the stated warranty period, the defective Equipment must be returned to a Radio Shack Computer Center, a Radio Shack retail store, participating Radio Shack franchisee or Radio Shack dealer for repair, along with a copy of the sales document or lease agreement. The original CUSTOMER'S sole and exclusive remedy in the event of a defect is limited to the correction of the defect by repair, replacement, or refund of the purchase price. at RADIO SHACK'S election and sole expense. RADIO SHACK has no obligation to replace or repair expendable items.
- B. RADIO SHACK makes no warranty as to the design, capacity, capacity, or suitability for use of the Software, except as provided in this paragraph. Software is licensed on an "AS IS" basis, without warranty. The original CUSTOMER'S exclusive remedy, in the event of a Software manufacturing defect, is its repair or replacement within thirty (30) calendar days of the date of the Radio Shack sales document received upon license of the Software The defective Software shall be returned to a Radio Shack Computer Center, a Radio Shack retail store, participating Radio Shack franchisee or Radio Shack dealer along with the sales document.
- C. Except as provided herein no employee, agent, franchisee, dealer or other person is authorized to give any warranties of any nature on behalf of RADIO SHACK.
- D. Except as provided herein, RADIO SHACK MAKES NO WARRANTIES, INCLUDING WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.
- E. Some states do not allow limitations on how long an implied warranty lasts, so the above limitation(s) may not apply to CUSTOMER

III. LIMITATION OF LIABILITY

- A. EXCEPT AS PROVIDED HEREIN, RADIO SHACK SHALL HAVE NO LIABILITY OR RESPONSIBILITY TO CUSTOMER OR ANY OTHER PERSON OR ENTITY WITH RESPECT TO ANY LIABILITY, LOSS OR DAMAGE CAUSED OR ALLEGED TO BE CAUSED DIRECTLY OR INDIRECTLY BY "EQUIPMENT" OR "SOFTWARE" SOLD, LEASED, LICENSED OR FURNISHED BY RADIO SHACK, INCLUDING, BUT NOT LIMITED TO, ANY INTERRUPTION OF SERVICE, LOSS OF BUSINESS OR ANTICIPATORY PROFITS OR CONSEQUENTIAL DAMAGES RESULTING FROM THE USE OR OPERATION OF THE "EQUIPMENT" OR "SOFTWARE" IN NO EVENT SHALL RADIO SHACK BE LIABLE FOR LOSS OF PROFITS, OR ANY INDIRECT, SPECIAL, OR CONSEQUENTIAL DAMAGES ARISING OUT OF ANY BREACH OF THIS WARRANTY OR IN ANY MANNER ARISING OUT OF OR CONNECTED WITH THE SALE. LEASE, LICENSE, USE OR ANTICIPATED USE OF THE "EQUIPMENT" OR "SOFTWARE" NOTWITHSTANDING THE ABOVE LIMITATIONS AND WARRANTIES, RADIO SHACK'S LIABILITY HEREUNDER FOR DAMAGES INCURRED BY CUSTOMER OR OTHERS SHALL NOT EXCEED THE AMOUNT PAID BY CUSTOMER FOR THE PARTICULAR "EQUIPMENT" OR "SOFTWARE" INVOLVED.
- B. RADIO SHACK shall not be liable for any damages caused by delay in delivering or furnishing Equipment and/or Software.
- C No action arising out of any claimed breach of this Warranty or transactions under this Warranty may be brought more than two (2) years after the cause of action has accrued or more than four (4) years after the date of the Radio Shack sales document for the Equipment or Software, whichever first occurs.
- D. Some states do not allow the limitation or exclusion of incidental or consequential damages, so the above limitation(s) or exclusion(s) may not apply to CUSTOMER

IV. RADIO SHACK SOFTWARE LICENSE

RADIO SHACK grants to CUSTOMER a non-exclusive, paid-up license to use the RADIO SHACK Software on one computer, subject to the following provisions:

- A. Except as otherwise provided in this Software License, applicable copyright laws shall apply to the Software.
- B. Title to the medium on which the Software is recorded (cassette and/or diskette) or stored (ROM) is transferred to CUSTOMER. but not title to the Software
- C CUSTOMER may use Software on one host computer and access that Software through one or more terminals if the Software permits this unction
- D. CUSTOMER shall not use. make, manufacture. or reproduce copies of Software except for use on one computer and as is specifically provided in this Software License. Customer is expressly prohibited from disassembling the Software.
- E. CUSTOMER is permitted to make additional copies of the Software only for backup or archival purposes or if additional copies are required in the operation of one computer with the Software, but only to the extent the Software allows a backup copy to be made. However. for TRSDOS Software, CUSTOMER is permitted to make a limited number of additional copies for CUSTOMER'S own use
- F. CUSTOMER may resell or distribute unmodified copies of the Software provided CUSTOMER has purchased one copy of the Software for each one sold or distributed. The provisions of this Software License shall also be applicable to third parties receiving copies of the Software from CUSTOMER
- G. All copyright notices shall be retained on all copies of the Software

V. APPLICABILITY OF WARRANTY

- A. The terms and conditions of this Warranty are applicable as between RADIO SHACK and CUSTOMER to either a sale of the Equipment and or Software License to CUSTOMER or to a transaction whereby RADIO SHACK sells or conveys such Equipment to a third party for lease to CUSTOMER
- The limitations of liability and Warranty provisions herein shall inure to the benefit of RADIO SHACK, the author, owner and/or licensor of the Software and any manufacturer of the Equipment sold by RADIO SHACK.

VI. STATE LAW RIGHTS

The warranties granted herein give the original CUSTOMER specific legal rights, and the original CUSTOMER may have other rights which vary from state to state

Disk EDTASM Software: Copyright 1983, Microsoft. All Rights Reserved. Licensed to Tandy Corporation.

Disk EDTASM Manual: Copyright 1983, Tandy Corporation. All Rights Reserved.

Reproduction or use without express written permission from Tandy Corporation, of any portion of this manual is prohibited. While reasonable efforts have been taken in the preparation of this manual to assure its accuracy, Tandy Corpdration assumes no liability resulting from any errors or omissions in this manual, or from the use of the information contained herein.

To Our Customers . . .

The heart of the Color Computer is a 6809E "processor." It controls all other parts of the Color Computer.

The processor understands only a code of 0s and 1s, not at all intelligible to the human mind. This code is called "6809 machine code."

When you run a BASIC program, a system called the "BASIC Interpreter" translates each statement, one at a time, into 6809 machine code. This is an easy way to program, but inefficient.

The Disk EDTASM lets you program using an intelligible representation of 6809 machine code, called "assembly language," that talks directly to the processor. You then assemble the entire program into 6809 machine code before running it.

Programming with the Disk EDTASM gives you these benefits:

- You have direct and complete control of the Color Computer. You can use its features - such as high resolution graphics - in ways that are impossible with BASIC.
- Your program runs faster. This is because it is already translated into 6809 machine code when you run it.

To Use the Disk EDTASM You Need ...

A Color Computer Disk System that has at least 16K of RAM, preferably 32K. (A 16K System will leave you little room for programs.)

The Disk EDTASM Contains:

EDTASM/BIN, a system for creating 6809 programs.
 EDTASM contains:

An editor, for writing and editing 6809 assembly language programs.

An assembler, for assembling the programs into 6809 machine code.

ZBUG, for examining and debugging 6809 machine-code programs.

You must have 32K to run EDTASM. If you have 16K, run EDTASMOV (described next).

- EDTASMOV/BIN, a memory-efficient version of EDT ASM consisting of overlays. EDTASMOV contains the editor and assembler, but not ZBUG.
- ZBUG/BIN, a stand-alone version of ZBUG, primarily for use with EDTASMOV.
- DOS/BIN, a disk operating system. DOS contains disk access routines that you can call from an assembly language program. (You cannot call BASIC's disk access routines with any program other than BASIC.)

EDTASM/BIN, EDTASMOV/BIN, and ZBUG/BIN all use DOS routines and must be run with DOS.

The Disk EDT ASM also contains:

- DOS/BAS. A BASIC program that loads DOS/BIN.
- ZBUG/BAS. A BASIC program that loads ZBUG/BIN.

How to Use this Manual

This manual is organized for both beginning and advanced assembly language programmers. *Sections I-IV* are tutorials; *Section V* is reference.

Beginning Programmers:

Read Section I first. It shows how the entire system works and explains enough about assembly language to get you started.

Then, read Sections II, III, and IV in any order you want. Use Section V, "Reference," as a summary.

This manual does not try to teach you 6809 mnemonics. To learn this, read:

Radio Shack Catalog #62-2077 by William Barden Jr.

6809 Assembly Language Programming by Lance A. Leventhal

Nor does it teach you disk programming concepts. To learn these, read:

Color Computer Disk System Manual (Radio Shack Catalog #26-3022)

Advanced Programmers:

First, read Chapters 1 and 2 to get started and see how the entire system works. Then, read Section V, "Reference."

You can use the DOS program listing to obtain information on routines and addresses not explained in this manual. Please note the following:

Radio Shack supports only these DOS routines: OPEN, CLOSE, READ, and WRITE. Additional DOS routines are listed in Reference H. However, Radio Shack does not promise to support them.

Even more DOS routines and addresses can be found in the program listing. However, Radio Shack does not promise to support them nor even provide them in the future.

For technical information on the Color Computer Disk System and 6809, refer to 6809 Assembly Language Programming and Color Computer Disk System Manual, listed above.

This manual uses these terms and notations:

To denote a key you must press.

Italics To denote a value you must supply.

filespec To denote a DOS file specification. A DOS filespec is in one of these formats:

filename/ext:drive filename.ext:drive

filename has one to eight characters. extension has one to three characters. drive is the drive number. If the drive number is omitted, DOS uses the first available drive.

\$ To denote a hexadecimal (Base 16) number. For example, \$OF represents hexadecimal OF, which is equal to 15 in decimal (Base 10) notation

SECTION I GETTING STARTED

SECTION I

GETTING STARTED

This section gets you started using the Disk EDTASM and explains some concepts you need to know.

Chapter 1/ Preparing Diskettes

Before using the Disk EDTASM, you need to format blank diskettes and back up the master Disk EDTASM diskette.

Formatting Blank Diskettes

- Power up your disk system and insert a blank diskette in Drive 0. (See the Color Computer Disk System Manual for help.)
- 2. At the OK prompt, type:

DSKINIØ ENTER

BASIC formats the diskette. When finished, it again shows the OK prompt.

Making Backups of Disk EDTASM

Single-Drive Systems

1. Insert the master Disk EDTASM diskette, your "source" diskette, in Drive 0.

- 2. At the BASIC OK prompt, type: BACKUP Ø TO Ø ENTER
- 3. BASIC then prompts you to insert the "destination" diskette. Remove the source diskette and insert a formatted diskette. ENTER
- 4. BASIC prompts you to alternatively insert the source, then destination diskettes. When the backup is finished, the OK prompt appears.

The destination diskette is now a duplicate of the master Disk EDTASM diskette.

Multi-Drive Systems

- 1. Insert the master Disk EDTASM diskette in Drive 0.
- 2. Insert a formatted diskette in Drive 1.
- 3. At BASIC's OK prompt, type:

BACKUP Ø TO 1 ENTER

BASIC makes the backup. When the backup is finished, the OK prompt appears.

The diskette in Drive 1 is now a duplicate of the master Disk EDTASM diskette.

Chapter 2/ Running a Sample Program

This "sample session" gets you started writing programs and shows how to use the Disk EDTASM. The next chapters explain why the program works the way it does.

1. Load and Run DOS

Insert the Disk EDTASM diskette in Drive O. At the OK prompt, type:

RUN "DOS" ENTER

DOS then loads and puts you in its "command mode." The screen shows the DOS command menu:

- 1. Exit to BASIC
- 2. Exec a Program
- 3. Start Clock Display
- 4. Disk Allocation Map
- 5. Copy Files
- 6. Directory

DOS consists of many disk input and output routines which EDTASM uses. You must load DOS before loading EDTASM.

2. Load and Run EDTASM

At the DOS Menu, press 2 to select "Execute a Program." The screen asks for the name of a program file.

If your system has 32K or more, use EDTASM. If it has only a 16K system, use EDTASMOV.

Loading EDTASM:

Type EDTASM. The screen shows:

EXECUTE A PROGRAM
PROGRAM NAME: [EDTASM]/BIN

If you make a typing error, use the \subseteq to reposition the cursor at the beginning of the line, then correct the mistake. Replace any trailing characters with blank spaces.

Press ENTER. EDTASM loads and shows its startup message.

Loading EDTASMOV:

Type EDTASMOV. The screen shows:

EXECUTE A PROGRAM
PROGRAM NAME: [EDTASMOVJ/BIN

If you make a mistake, use the $ext{ } ext{ } ext{$

EDTASMOV loads and shows its startup message.

Always keep EDTASMOV in Drive 0. It contains overlays which it loads into memory as required. It always looks for these overlays in Drive 0.

3. Type the Source Program

Notice the asterisk(*) prompt. This means you are in the editor program of EDTASM or EDTASMOV. The editor lets you type and edit an assembly language "source" program.

At the * prompt, type:

I ENTER

This puts you in the editor's insert mode. The editor responds with line number 00100. Type:

STARTDLOAD#\$F9ENTER

The right arrow tabs to the next column. ENTER inserts the line in the editor's "edit buffer." The \$ means that F9 is a hexadecimal (Base 16) number.

Your screen should show:

00100 START LOA #\$F9 00110

meaning that you inserted line 100 and can now insert line 110.

If you make a mistake, press BREAK Then, at the * prompt, delete Line 100 by typing:

D100 ENTER

Now, insert Line 100 correctly in the same manner described above.

Insert the entire assembly language program listed below.

Note that line 150 uses brackets. Do not substitute parentheses for the brackets. To produce the left bracket, press SHIFT and 12 at the same time. To produce the right bracket, press SHIFT and 13 at the same time.

00100	START	LOA	#\$FS
00110		LOX	#\$400
00120	SCREEN	STA	1 X +
00130		CMP#	\$800
00140		BNE	SCREEN
00150	WAIT	JSR	[\$A000]
00160		BEQ	WAIT
00170		CLR	\$71
00180		JMP	[\$FFFE]
00190	DONE	EQU	*
00200		END	

If you make a mistake, press BREAK Then, at the * prompt, delete the program by typing:

D#:*

Now, insert the program correctly.

When finished, press **BREAK**. The program you have inserted is an assembly language "source" program, which we'll explain in the next chapter.

4. Assemble the Source Program in Memory

At the * prompt, type:

A/IM/WE ENTER

which loads the assembler program. The assembler then assembles your source program into 6809 machine code

into the memory area just above the EDTASM or EDTAS-MOV program. To let you know what it has done, it prints this listing:

4B28_BG		00100	START	
LDA 482A BE 107	#\$F9 0400 #\$400	00110		
482D A7 STA	8Ø 1X+	00120	SCREEN	
4B2F BC	0800 #\$800	00130		
4B32 28 BNE		00140		
	SCREEN 9F A000 [\$A000]	00150	WAIT	
4B38 27 BEQ	FA	00160		
4B3A ØF CLR	71	00170		
4B3C 6E	9F FFFE [\$FFFE]	00180		
EQU *		00190	DONE	
END	0000 0020	ð Ø		
00000 TOTAL ERRORS				
DONE 4840 SCREEN 4820 START 4820 WAIT 4830	0 8			

(If using EDTASMOV, the numbers will be different.)

If the assembler does not print this entire listing, but stops and shows an error message instead, you have an error in the source program. Repeat Steps 3 and 4.

The assembler listing is explained in *Figure 1* of *Chapter 7*.

5. Prepare the Program for DOS

Before saving the program, you need to prepare it so that you can load and run it from DOS.

First, you must give it an "origination address" for DOS to use in loading the program back into memory. (We recommend you use Address \$1200, the first address

available after the DOS system.) To do so, type:

ISØ ENTER

and insert this line:

50 ORG \$1200

Next, you need to add two lines to your program to tell DOS how long the program is. Insert these lines:

60 BEGIN JMP START

70 FDB DONE-BEGIN

When finished, press **BREAK**. To see the entire program, type:

P#: * ENTER

It should look like this:

00050		ORG	\$1200
00060	BEGIN	JMP	START
00070		FDB	DONE-BEGIN
00100	START	LDA	#\$F9
00110		LDX	#\$400
00120	SCREEN	STA	,X+
00130		CMPX	#\$600
00140		BNE	SCREEN
00150	WAIT	JSR	[\$A000]
00160		BEQ	WAIT
00170		CLR	\$71
00180		JMP	[\$FFFE]
00180	DONE	EQU	*
00200		END	

If you make a mistake, delete the line with the error and insert it again.

6. Save the Source Program on Disk

To save the source program, type (at the* prompt):

WD SAMPLE ENTER

This saves the source program on disk as SAMPLE/ASM.

7. Save the Assembled Program on Disk

At the * prompt, type:

AD SAMPLE /SR ENTER

Be sure you have a blank space between SAMPLE and /SR. This causes the assembler to again assemble the source program into 6809 code. This time, the Assembler saves the assembled program on disk as SAMPLE/BIN.

(You must use the /SR "switch" to assemble any program that you want to load and run from DOS.)

8. Run the Assembled Program from DOS

To run the assembled program, you need to be in the DOS command mode. At the * prompt, type:

K ENTER

which causes the Editor to return you to the DOS command menu. Press (2) to execute a program. Then type SAMPLE, the name of the assembled program. (The assembler assumes you mean SAMPLE/BIN.) The screen shows:

EXECUTE A PROGRAM
PROGRAM NAME: [SAMPLE]/BIN

Press ENTER. The SAMPLE program executes, filling your entire screen with a graphics checkerboard. Press any key to exit the program. The program returns to BASIC startup message.

9. Debug the Program (if necessary)

ZBUG lets you to look at memory. How you load ZBUG depends on whether you are using EDTASM or EDTAS-MOV.

EDTASM Users:

You can load ZBUG from EDTASM. Load DOS and EDTASM again (Steps 1 and 2). Then, at the * prompt, type:

Z ENTER

EDT ASM loads its ZBUG program and displays ZBUG's #prompt. You can now examine any memory address. Type:

4000/

In Chapter 8, we'll show you how to use ZBUG to examine and test your program. To return to EDTASM's editor, type:

E (ENTER)

EDTASMOV Users:

You must use the Stand-Alone ZBUG. Load DOS again (Step 1). At the DOS Menu, press 2, "Execute a Program," and run the ZBUG program. After typing ZBUG, the screen shows:

EXECUTE A PROGRAM
PROGRAM NAME: [ZBUG]/BIN

DOS loads the stand-alone ZBUG and displays ZBUG's #prompt. You can now examine any memory address. Type:

3800/

In Chapter 8, we'll show you how to use ZBUG to examine and test your program. To return to DOS, type:

K ENTER SPACEBAR

Chapter 3/ Overview

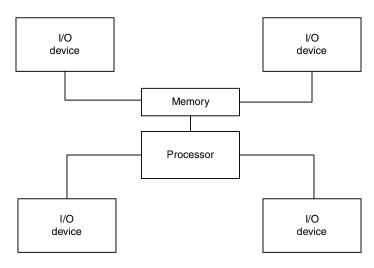

This chapter is for beginning assembly language programmers. It explains some concepts you need. If you're not a beginner, use this chapter as a refresher or skip it.

The Color Computer Hardware

The Color Computer consists of:

- The 6809E Processor
- Memory
- Input/Output Devices

This shows how they relate to each other:

The Processor

The processor processes all data going to each memory address and device. It contains:

- Registers for temporarily storing 1- or 2-byte values.
- Buses for transferring data to or from the processor.

All instructions to the processor must be in 6809 machine

code: a code of Os and 1 s containing "opcodes" and data. "Opcodes" are instructions that tell the processor to manipulate data in some way.

For example, the machine-code instruction "10000110 11111001" contains:

- The opcode "10000110" (decimal 134 or hexadecimal 86)
- The data "11111001" (decimal 249 or hexadecimal F9)

This instruction tells the processor to load Register A with 11111001.

Memory

Memory is a storage area for programs and data. There are two kinds of memory:

- Random access memory (RAM) for temporary storage of programs or data. When you load a program from disk, you load it Into RAM. Many opcodes store data in RAM temporarily.
- Read only memory (ROM) for permanent storage of programs. BASIC, as well as any program pack you use, is stored in ROM. The Color Computer contains several "ROM routines" that you can use to access the keyboard, screen, or tape recorder.

When writing an assembly language program, you must constantly be aware of what's happening in memory. For this reason, this manual provides a memory map. (See Reference J.)

Devices

All other parts of the hardware are called devices. A device expects the processor to input or output data to it in a certain format. To input or output data in this format, you can use these pre-programmed subroutines:

- Routines stored in ROM (ROM routines) for inputting or outputting to the keyboard, screen, printer, or tape recorder.
- Routines stored in DOS (DOS routines) for inputting or outputting to disk.

The Disk EDTASM Assembler

The Disk EDT ASM looks for three fields in your instructions: label, command, and operand. For example, in this instruction:

BEGIN JMP START

BEGIN is the label. JMP is the command. START is the operand.

In the label field, it looks for:

Symbols (symbolic names)

In the command field, it looks for:

- Mnemonics
- Pseudo Ops

In the operand field, it looks for:

- Symbols
- Operators
- Addressing-Mode Characters
- Data

Symbols

A symbol is similar to a variable. It can represent a value or a location. BEGIN (in the sample session) is a symbol that represents the location of the instruction JMP START. START is also a symbol that represents the location of LOA #\$F9.

Mnemonics

A mnemonic is a symbolic representation of an opcode. It is a command to the processor. "LOA" is a mnemonic. Depending on which "addressing-mode character" you use, LOA represents one of these opcodes:

10000110

10010110

10110110

10100110

(Addressing-mode characters are discussed below.) Mnemonics are specific to a particular processor. For example, Radio Shack's Model 4 uses the zao processor, which understands zao mnemonics, rather than the 6809

mnemonics.

Pseudo Ops

A pseudo op is a command to the assembler. END (in the sample session) is a pseudo op. It tells the assembler to quit assembling the program.

Data

Data is numbers or characters. Many of the mnemonics and pseudo ops call for data. Unless you use an operator (described next), the assembler interprets your data as a decimal (Base 10) number.

Operators

An operator tells the assembler to perform a certain operation on the data. In the value \$1200, the \$ sign is an operator. It tells the assembler that 1200 is a hexadecimal (Base 16) number, rather than a decimal (Base 10) number.

The more commonly used operators are arithmetic and relational. Addition (+) and equation (=) are examples of these operators.

Addressing-Mode Characters

An addressing mode character tells the assembler how it should interpret the mnemonic. The assembler then assembles the mnemonic into the appropriate opcode.

The sample session uses the # character with the LOA mnemonic to denote the "immediate" addressing mode. This causes the assembler to assemble LOA into the opcode 10000110.

The immediate mode means that the number following the mnemonic (in this case, \$F9) is data rather than an address where the data is stored.

Pseudo ops, symbols, operators, and addressing-mode characters vary from one assembler to another. Section III explains them in detail.

Sample Program

This is how each line in the sample program works:

50

ORG

\$1200

ORG is a pseudo op for "originate." It tells the assembler to begin loading the program at Location \$1200 (Hexadecimal 1200). This means that when you load and run the program from DOS, the program starts at Memory Address \$1200.

60

BEGIN

JMP

START

BEGIN is a symbol. It equals the location where the JMP START instruction is stored.

JMP is a mnemonic for "jump to an address." It causes the processor to jump to the location of the program labeled by the symbol START, which is the LOA #\$F9 instruction. You must use JMP or LBRA as the first instruction in a DOS program.

70

FDB

DONE-BEGIN

FDB is a pseudo op for "store a 2-byte value in memory." It stores the value of DONE-BEGIN (the length of the program) in the next two bytes of memory. You must store this value at the beginning of the program to tell DOS how much of the program to load.

00100

START

LDA

#\$F9

START is a symbol. It equals the location where LDA #\$F9 is stored.

LDA is a mnemonic for "load Register A." It loads Register A with \$F9, which is the hexadecimal ASCII code for a graphics character. The ASCII characters are listed in Reference K.

00110

LDX

#\$400

LDX is a mnemonic for "load Register X." It loads Register X with \$400, the first address of video memory. Reference J shows where video memory begins and ends.

00120

SCREEN STA

,X+

SCREEN is a symbol. It equals the location where STA .X+ is stored.

STA is a mnemonic for "store Register A." It stores the contents of Register A (\$F9) in the address contained in Register X (\$400). This puts the \$F9 graphics character at the upper left corner of your screen.

The "," and " + " are addressing-mode characters. The , causes the processor to store \$F9 in the address contained in Register X. The + causes the processor to then

increment the contents of Register X to \$401.

00130

CMPX

#\$600

CMPX is a mnemonic for "compare Register X." It compares the contents of Register X with \$600. If Register X contains \$600, the processor sets the "Z" bit in the Register CC to 1.

00140

BNE

SCREEN

BNE is a mnemonic for "branch if not equal." It tells the processor return to SCREEN (the STA,X + instruction) until the Z bit is set.

The BNE SCREEN instruction creates a loop. The program branches back to SCREEN, filling all video memory addresses with \$F9, until it fills Address \$600. At that time, Register X contains \$600, Bit Z is set, and program control continues to the next instruction.

00150

WAIT

JSR [\$A000]

JSR is a mnemonic for "jump to a subroutine." \$A000 is a memory address that stores the address of a ROM routine called POLCAT. (See Reference F.)

POLCAT scans the keyboard to see if you press a key. When you do, it clears the Z bit.

The "[]" are addressing-mode characters. They tell the processor to use an address contained in an address, rather than the address itself. Always use the "[]" signs when calling ROM routines.

00160

BEQ

WAIT

BEQ is a mnemonic for "branch if equal." It branches to the JSR [\$AOOO] instruction until the Z bit is clear. This causes the program to loop until you press a key, at which time POL CAT clears the Z bit.

00170

C1

\$71

00180

JMP

[\$FFFE]

CLR is a mnemonic for "clear," and JMP is a mnemonic for "jump to memory address." These two instructions end the program and return to BASIC's startup message.

(CLR inserts a zero in Address \$71; this signals that the system is at its original "uninitialized" condition. JMP goes to the address contained in Address \$FFFE; this is where BASIC initialization begins.)

00180

DONE

EQU

EQU is a pseudo op. It equates the symbol DONE with an asterisk (*), which represents the last line in the program.

3 / OVERVIEW

00190 END

END is a psuedo op. It tells the assembler to quit assembling the program.

SECTION II COMMANDS

SECTION II

COMMANDS

This section shows how to use the many Disk EDTASM commands. Knowing these commands will help you edit and test your program.

Chapter 4/ Using the DOS Menu (DOS Commands)

When you first enter DOS, a menu of six DOS commands appear on the screen. Chapter 2 shows how to use the first two DOS commands. This chapter shows how to use the remaining commands:

- Start Clock Display
- Disk Allocation Map
- Copy Files
- Directory

To use the examples in this chapter, you need to have the SAMPLE disk files, which you created in Chapter 2, on the diskette in Drive 0.

Directory

The DOS "directory" command lets you select the directory entries you want to see, using three fields: filename, extension, and drive number.

To select the directory entries, press \blacksquare at the DOS Menu. Then, press the \blacksquare to move the cursor left or \blacksquare to move right.

Type this line to select all directory entries that have the filename SAMPLE.

```
[SAMPLE**] [***] :[0] <FILE SPEC
```

Use the .SPACEBARI to erase characters. Press ENTER when finished. Then, press any key to return to the DOS menu, and press © to return to the directory.

Type this line to select all directory entries with the extension /BIN:

```
[****** [BIN] : [0] <FILE SPEC
```

Press ENTER when finished. Return to the main menu.

To see all directory entries on the disk in Drive 0, simply press ENTER without specifying a filename or extension:

```
[******* [***] : [0] <FILE SPEC
```

Disk Allocation Map

The "disk allocation map" command tells you how much free space you have on your diskettes. To see the map, press 4 at the DOS menu.

DOS shows a map of the diskettes that are in each drive. The map shows how each of the diskette's 68 granules is allocated:

- A period (.) means the granule is free.
- An X means all the sectors in the granule are currently allocated to a file.
- A number indicates how many sectors in the granule are currently allocated to a file.

Press any key to return to the DOS menu.

Copy Files

The "Copy Files" command makes a duplicate of a disk file. To use it, press **5** at the DOS menu. DOS then prompts you for the names of the files.

Single-Drive Copy

The first example copies SAMPLE/ASM to another file named COPY/ASM. Use the \blacksquare and \boxdot to position the cursor. Answer the prompts as shown:

```
Source File Name
                         [SAMPLE
                                  ]
                         [ASM]
Extension
Drive
                         [0]
                         [COPY
Destination File Name
                                   ]
Extension
                         [ASM]
Drive
                         [0]
If Drives are the same are you
using different diskettes?
     ( Y or N )?
```

When finished, press ENTER. DOS copies SAMPLE/ ASM to a new file named COPY/ASM and then returns to the DOS menu. Check the directory (by pressing (a)) and you'll see that both SAMPLE/ASM and COPY/ASM are on your diskette.

The next example copies SAMPLE/ASM to another diskette. Answer the prompts as shown:

```
Source File Name
                        SAMPLE
                                 1
   Extension
                        [ASM]
   Drive
                        [0]
Destination File Name
                        [COPY
                                ]
   Extension
                        [ASM]
   Drive
                        ΓØ7
If Drives are the same are you
using different diskettes?
(Y or N)?
                TY1
```

Press ENTER. DOS then prompts you to insert the source diskette. Press ENTER again.

DOS then prompts you for a destination diskette. Insert the destination diskette and press ENTER. After copying the file, DOS prompts you for a system diskette. If you press ENTER without inserting a system diskette, you will get a SYSTEM FAILURE error.

When finished, it returns to the DOS menu.

Multi-Drive Copy

This example copies SAMPLE/ASM in Drive 0 to SAM-PLE/ASM in Drive 1. Answer the prompts as shown:

```
SAMPLE
Source File Name
                        [ASM]
   Extension
   Drive
                         [0]
Destination File Name
                         [SAMPLE
                                  1
                         [ASM]
   Extension
                        T 1 T
   Orive
If Drives are the same are you
using different diskettes?
( Y or N )?
                 ΓNΊ
```

Start Clock Display

The Color Computer has a clock that runs on 60-cycle interrupts. Since the clock skips a second or more when the computer accesses tape or disk, we recommend that you not use it while executing a program.

To use the clock, press ③, "Start Clock Display." Six digits appear at the upper right corner of your screen. The first two are hours, the next are minutes, and the next are seconds. This clock counts the time until you exit DOS.

Chapter 5/ Examining Memory ZBUG Commands — Part I

To use the Disk EDTASM, you must understand the Color Computer's memory. You need to know about memory to write the program, assemble it, debug it, and execute it.

In this chapter, we'll explore memory and see some of the many ways you can get the information you want. To do this, we'll use ZBUG.

If you are not "in" ZBUG, with the ZBUG # prompt displayed, you need to get in it now.

EDTASM: Load and run DOS, then execute the EDTASM program. At the editor's* prompt, type:

Z ENTER

EDTASMOV: Load and run DOS, then execute the ZBUG program.

You should now have a# prompt on your screen. This means you are in ZBUG and you may enter a ZBUG command. All ZBUG commands must be entered at this command level. You can return to the command level by pressing BREAK or ENTER.

Examining a Memory Location

The 6809 can address 65,536 one-byte memory addresses, numbered 0-65535 (\$0000-\$FFFF). We'll examine Address \$AOOO. At the# prompt, type:

B ENTER

to get into the "byte mode." Then type:

A000/

and ZBUG shows the contents of Address \$AOOO. To see the contents of the next bytes, press \blacksquare . Use \blacksquare to scroll to the preceding address.

All the numbers you see are hexadecimal (Base 16). You see not only the 10 numeric digits, but also the 6 alpha characters needed for Base 16 (A-F). Unless you specify another base (which we do in Chapter 9), ZBUG assumes you want to see Base 16 numbers. Notice that a zero precedes all the hexadecimal numbers that begin with an alphabetic character. This is done to avoid any confusion between hexadecimal numbers and registers.

Examination Modes

To help you interpret the contents of memory, ZBUG offers four ways of examining it:

- Byte Mode
- Word Mode
- ASCII Mode
- Mnemonic Mode

Byte Mode

Until now, you've been using the byte mode. Typing B ENTER. at the # prompt got you into this mode.

The byte mode displays every byte of memory as a number, whether it is part of a machine-language program or data.

Word Mode

Type ENTER to get back to the # prompt. To enter the word mode, type:

III ENTER

Look at Address \$A000 again by typing:

A000/

Note the contents of this address "word." This is the address where POLCAT, a ROM routine, is stored. Examine the POLCAT routine. For example, if \$A000 contains A1C1, type:

A1C1/

and you'll see the contents of the first two bytes in the POLCAT routine. We'll examine this routine later in this chapter using the "mnemonic mode."

ASCII Mode

Return to the command level. To enter the ASCII mode, type:

A ENTER

ZBUG now assumes the content of each memory address is an ASCII code. If the "code" is between \$21 and \$7F, ZBUG displays the character it represents. Otherwise, it displays meaningless characters or "garbage."

Here, the $\ensuremath{\,\underline{\vee}\,}$ increments the address by one.

Mnemonic Mode

This is the default mode. Unless you ask for some other mode, you will be in the default mode.

Return to the # prompt. To enter the mnemonic mode from another mode, type:

M (ENTER)

Look at the addresses where the POLCAT routine is

stored. For example, if you found that POLCAT is at address \$A1C1, type:

A1C1/

For example, assume the first two addresses in POLCAT contain \$3454. \$3454 is an opcode for the PSHS U,X,B mnemonic. Therefore, ZBUG disassembles \$3454 into PSHS U,X,B.

Begin the disassembly at a different byte. Press BREAK and then examine the address of POLCAT plus one. For example, if POLCAT starts at address \$A1C1, type:

A1C2/

You now see a different disassembly. The contents of memory have not changed. ZBUG has, however, interpreted them differently.

For example, assume \$A1C2 contains a \$54. This is the opcode for the LSRB mnemonic. Therefore, ZBUG disassembles \$54 into LSRB.

To see the program correctly, you must be sure you are beginning at the correct byte. Sometimes, several bytes will contain the symbol "??". This means ZBUG can't figure out which instruction is in that byte and is possibly disassembling from the wrong point. The only way of knowing you're on the right byte is to know where the program starts.

Changing Memory

As you look at the contents of memory addresses, notice that the cursor is to the right. This allows you to change the contents of that address. After typing the new contents, press ENTER or T; the change will be made.

To show how to change memory, we'll open an address in video memory. Get into the byte mode and open Address \$015A by typing:

BREAK B BREAK

Note that the cursor is to the right. To put a 1 in that address, type:

1 ENTER

If you want to change the contents of more than one address, type:

015A/

Then type:

The size of the changes you make depends on the examination mode you are in. In the byte mode, you will change one byte only and can type one or two digits.

In the word mode, you will change one word at a time. Any 1-, 2-, 3-, or 4-digit number you type will be the new value of the word.

If you type a hexadecimal number that is also the name of a 6809 registers (A,B,D,CC,DP,X,Y,U,S,PC), ZBUG assumes it's a register and gives you an "EXPRESSION ERROR." To avoid this confusion, include a leading zero (0A,0B, etc.)

To change memory in the ASCII mode, use an apostrophe before the new letter. For example, here's how to write the letter C in memory at Address \$015A. To get into the ASCII examination mode, type:

Αе

To open Address \$015A,type:

015A/

To change its contents to a C, type:

¹ □ ↓

Pressing the \blacksquare will assure you that the address contains the letter C.

If you are in mnemonic mode, you must change one to five bytes of memory depending on the length of the opcode. Changing memory is complex in mnemonic mode because you must type the opcodes rather than the mnemonic.

For example, get into the mnemonic mode and open Address \$015A. Type:

MENTER

015A/

To change this instruction, type:

86 ENTER

Now Address \$015A contains the opcode for the LDA mnemonic. Open location 015B:

0158/

and insert \$06, the operand:

Ø6 ENTER

Upon examining Address \$015A again, you'll see it now contains an LOA #6 instruction.

Exploring the Computer's Memory

You are now invited to examine each section of memory using ZBUG commands to change examination modes. Use the Memory Map in *Reference J.*

Don't hesitate to try commands or change memory. You can restore anything you alter simply by removing the diskette and turning the computer off and then on again.

Chapter 6/ Editing the Program Editor Commands

The editor has many commands to help you edit your source program. *Chapter 2* shows how to enter a source program. This chapter shows how to edit it.

To use the edit commands you must return to the editor from ZBUG:

EDTASM: From EDTASM ZBUG, return to the editor by typing E ENTER

EDTASMOV: From Stand-Alone ZBUG, return to the DOS menu by typing K ENTER). Then, execute the EDTASMOV program.

The screen now shows the editor's * prompt. While in the editor, you can return to the * prompt at any time by pressing BREAK.

This chapter uses SAMPLE/ASM from Chapter 2 as an example. To load SAMPLE/ASM into the editor, type:

L SAMPLE/ASM ENTER

Print Command Prange

To print a line of the program on the screen, type:

P100ENTER

To print more than one line, type:

P100: 130 ENTER)

You will often refer to the first line, last line, and current line (the last line you printed or inserted). To make this easier, you can refer to each with a single character:

- # first line
- * last line
- current line (the last line you printed or inserted.)

To print the current line, type:

P. (ENTER)

To print the entire text of the sample program, type:

P#:*ENTER

This is the same as P050:200 e.

The colon separates the beginning and ending lines in a range of lines. Another way to specify a range of lines is with!. Type:

P#! 5 ENTER

and five lines of your program, beginning with the first one, are printed on the screen.

To stop the listing while it is scrolling, quickly type:

SHIFT @

To continue, press any key.

Printer Commands Hrange

Trange

If you have a printer, you can print your program with the H and T commands. The H command prints the editorsupplied line numbers. The T command does not.

To print every line of the edit buffer to the printer, type:

H#: * ENTER

You are prompted with:

PRINTER READY

Respond with **ENTER** when ready.

The next example prints six lines, beginning with line 100, but without the editor-supplied line numbers. Type:

T100! 6 ENTER

Edit Command

Eline

You can edit lines in the same way you edit Extended

COLOR BASIC lines. For example, to edit line 100, type:

E 100 ENTER

The new line 100 is displayed below the old line 100 and is ready to be changed.

Press the to position the cursor just after START. Type this insert subcommand:

I E D ENTER

which inserts ED in the line.

The edit subcommands are listed in Reference A.

Delete Command

Drange

If you are using the sample program, be sure you have written it on disk before you experiment with this command. Type:

D110:140e

Lines 110 through 140 are gone.

Insert Command Istartline, Increment

Type:

I152,2ENTER

You may now insert lines (up to 127 characters long) beginning with line 152. Each line is incremented by two. (The editor does not allow you to accidently overwrite an existing line. When you get to line 160, it gives you an error message.)

Press BREAK to return to the command level. Then type:

I200 ENTER

This lets you begin inserting lines at the end of the program. Each line is incremented by two, the last increment you used.

Type:

ENTER I

The editor begins inserting at the current line.

On startup, the editor sets the current line to 100 and the increment to 10. You may use any line numbers between and 63999.

Renumber Command

Nstartline,Increment

Another command that helps with inserting lines between the lines is N (for renumber). From the command level, type:

N100,50 ENTER

The first line is now Line 100 and each line is incremented by 50. This allows much more room for inserting between lines.

Type:

™ ENTER

The current line is now the first line number. Renumber now so you will be ready for the next instruction. Type:

N100,10 ENTER

Replace Command Rstartline,Increment

The replace command is a variation of the insert command. Type:

R100,3e

You may now replace line 100 with a new line and begin inserting lines using an increment of three.

Copy Command

Cstartline,range,Increment

The copy command saves typing by duplicating any part of your program to another location in the program.

To copy lines, type:

C500,100:150,10ENTER

This copies lines 100 to 150 to a new location beginning at Line 500, with an increment of 10. An attempt to copy lines over each other will fail.

ZBUG Command

The EDTASM system contains a copy of the stand-alone ZBUG program. This allows you to enter ZBUG while your program is still in memory.

EDTASMOV Users: You need to use the StandAlone ZBUG program, as shown in *Chapter 2*.

To enter ZBUG, type:

ZENTER

The # prompt tells you that you are now in ZBUG.

To re-enter the editor from ZBUG, type the ZBUG command:

E ENTER

If you print your program, you'll see that entering and exiting ZBUG did not change it.

BASIC Command

To enter BASIC from the editor, type:

[ENTER]

If you want to enter DOS from the editor, type:

ENTER

Entering DOS or BASIC empties your edit buffer. Reentering the editor empties your BASIC buffer.

Write Command WD *filespec*

This command is the same one you used in Chapter 2 to write the source program to disk. It saves the program in a disk file named filespec. Filespec can be in one of these forms:

filename/ext:drive filename.ext:drive

The *filename* can be one to eight characters. It is required.

The *extension* can be one to three characters. It is optional. If the extension is omitted, the editor assigns the file the extension /ASM.

The *drive* can be a number from O to 4. It is also optional. If the drive number is omitted, the editor uses the first available drive.

Examples:

WD TESTENTER

saves source file currently in memory as TEST/ ASM.

WD TEST/PR1

saves the source file currently in memory as TEST/PR1.

Load Command

LD filespec LDA filespec

This command loads a source *filespec* from disk into the edit buffer. If the source *filespec* you specify does not have an extension, the editor uses /ASM.

If you don't specify the A option, the editor empties the edit buffer before loading the file.

If you specify the A option, the editor appends the file to the current contents of the edit buffer.

Appending files can be useful for chaining long programs.

When the second file is loaded, simply renumber the file with the renumber command.

Examples:

LD SAMPLE:1

empties the edit buffer, then loads a file named SAMPLE/ASM from Drive 1.

LDA SAMPLE/PRO

loads a file named SAMPLE/PRO from the first available drive, then appends to the current contents of the edit buffer.

The editor has several other commands. These are listed in *Reference A*.

Hints on Writing Your Program

- Copy short programs from any legal source available to you. Then modify them one step at a time to learn how different commands and addressing modes work. Try to make the program relocatable by using indexed, relative, and indirect addressing (described in Section III).
- Try to write a long program as a series of short routines that use the same symbols. They will be easier to understand and debug. They can later be combined into longer routines.

Note: You can use the editor to edit your BASIC programs, as well as assembly language programs. You might find this very useful since the EDT ASM editor is much more powerful than the BASIC editor. You need to first save the BASIC program in ASCII format:

SAVE filespec, A

Then, load the program into the editor.

Chapter 7/ Assembling the Program (Assembler Commands)

To load the assembler program and assemble the source program into 6809 machine code, EDTASM (or EDTASMOV) has an "assembly command." Depending on how you enter the command, the assembler:

- Shows an "assembly listing" giving information on how the assembler is assembling the program.
- Stores the assembled program in memory.
- Stores the assembled program on disk.
- Stores the assembled program on tape.

This chapter shows the different ways you can control the assembly listing, the in-memory assembly, and the disk assembly. Knowing this will help you understand and debug a program.

The Assembly Command

The command to assemble your source program into 6809 machine code is:

Assembling in memory:

A /IM /switch2/switch3/ ...

The /IM (in memory) switch is required.

Assembling to disk:

A filespec /switch1/switch2 ...

The assembled program is stored on disk as filespec. If filespec does not include an extension, the assembler uses /BIN.

Assembling to tape:

A filename /switch1/switch2/ ...

The assembled program is stored on tape as filename.

The *switch* options are as follows:

/AO Absolute origin

/IM Assemble into memory

/LP Assembler listing on the line printer

/MO Manual origin

/NL No listing

/NO No object code in memory or disk

/NS No symbol table in the listing

/SR Single record /SS Short screen

/SS Short screen listing
/WE Wait on assembly errors

/WS With symbols

You may use any combination of the switch options. Be sure to include a blank space before the first switch. If you omit filespec, you must use the in-memory switch (/IM).

Examples:

A/IM/WE

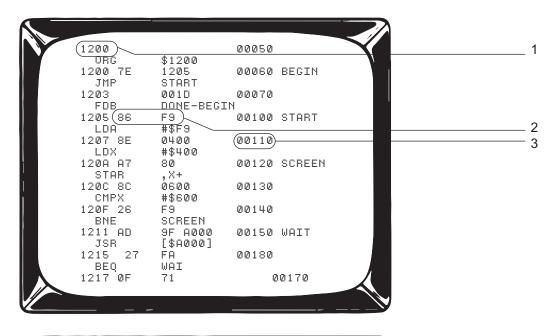

assembles the source program in memory (/IM) and stops at each error (/WE).

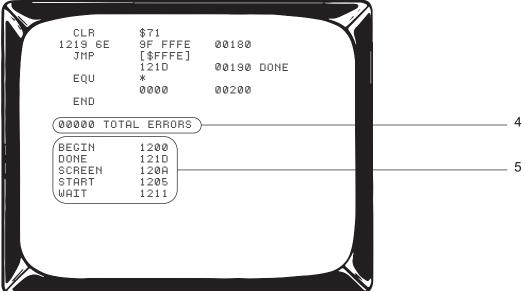

A TEST /LP

assembles the source program and saves it on disk as TEST/BIN. The listing is printed on the printer (/LP). Note that there must be a space between the filespec and the switch.

A TEST/PRO

assembles the source program and saves it on disk as ATEST/PRO.

- 1. The location in memory where the assembled code will be stored. In this example, the assembled code for LDA#\$F9 will be stored at hexadecimal location #1200.
- 2. The assembled code for the program line. \$86F9 is the assembled code for LOA #\$F9.
- 3. The program line.
- 4. The number of errors. If you have errors, you will want to assemble the program again with the /WE switch.
- 5. The symbols you used in your program and the memory locations they refer to.

Figure 1. Assembly Display Listing

Controlling the Assembly Listing

The assembler normally displays an assembly listing similar to the one in *Figure 1*. You can alter this listing with one of these switches:

/SS Short screen listing

/NS No symbol table in the listing

/NL No fisting

/LP Listing printed on the printer

For example:

A SAMPLE /NS

assembles SAMPLE and shows a listing without the symbol table.

If you are printing the listing on the printer, you might want to set different parameters. You can do this with the editor's "set line printer parameters" command:

To use this command, type (at the* prompt):

S ENTER

The editor shows you the current values for:

- LINCNT the number of lines printed on each page. ("line count")
- PAGLEN the number of lines on a page. ("page length")
- PAGWID the number of columns on a page. ("page width")
- FLDFLG the "fold flag" (This flag should contain 1 if your printer does not "wrap around." Otherwise, the flag should contain 0.)

It then prompts you for different values. Check your printer manual for the appropriate parameters. If you want the value to remain the same, simply press <code>ENTER</code>.

For example:

LINCHT=58 PAGLEN=BB PAGWID=BØ FLDFLG=0

sets the number of lines to 58, the page length to 66, and the page width to 80 columns. You can then assemble the program with the /LP switch:

A SAMPLE /LP

and the assembler prints the listing on the line printer using the parameters just set.

In-Memory Assembly The /IM Switch

The /IM switch causes the program to be assembled in memory, not on disk or tape. This is a good way to find errors in a program.

Where in memory? This depends on whether you use the /IM switch alone or accompany it with an ORG instruction, an /AO switch, or an /MO switch.

Using the /IM Switch Alone

This is the most efficient use of memory. The assembler stores your program at the first available address after the EDTASM (or EDTASMOV) program, the edit buffer, and the symbol table:

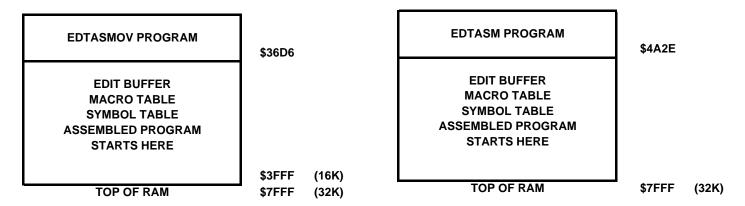

Figure 2. In-Memory Assembly

The EDTASM program ends at Address \$4A2D. The EDT ASMOV program ends at \$36D5.

The edit buffer contains the source program. It begins at Address \$4A2E or \$36D6 and varies in size depending on your program's length.

The macro table references all the macro symbols in your program and their corresponding values. (Macros are described in Chapter 12.) Its size varies depending on how many macros your program contains.

The symbol table references all your program's symbols and their corresponding values. Its size varies depending on how many symbols your program contains.

Example:

Load the SAMPLE/ASM back into the edit buffer. At the* prompt, type:

L SAMPLE/ASMENTER

Delete the ORG line. At the * prompt, type:

D50e

Then assemble the program in memory by typing:

A/IMe

(If you want another look, type A/IM again. You can pause the display by pressing SHIFT and continue by pressing any key.)

Since this sample program uses START to label the beginning of the program, you can find its originating address from the assembler listing. If you are using EDTASM, it should begin at Address \$4B1E. If you are using EDTASMOV, it should begin at \$37C6.

EDTASMOV PROGRAM \$36D6 EDIT BUFFER MACRO TABLE SYMBOL TABLE \$3800 ASSEMBLED PROGRAM STARTS HERE \$3FFF (16K) TOP OF RAM \$7FFF (32K)

Using ORG with /IM for Origination Offset

If you have an ORG instruction in your program and do not use the AO switch, the assembler stores your program at:

The first available address + the vplue of ORG

Example:

Insert this line at the beginning of the sample program:

EDTASM Systems:

0050 DRG \$6000

EDTASMOV Systems:

0050 ORG \$3800

Then, at the * prompt, type:

A/IMENTER

The START address is now the first available address + \$6000 or \$3800. This means that if you have less than 32K (with EDT ASM) or less than 16K (with EDTASMOV), the program extends past the top of RAM and you will get a BAD MEMORY error.

Using IM with /AO for Absolute Origin

The AO switch causes the assembler to store your program "absolutely" at the address specified by ORG.

With the ORG instruction inserted, type (at the * prompt):

A/IM/ADe

Your program now starts at address \$6000 or \$3800:

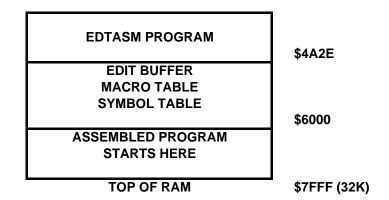

Figure 3. /AO In-Memory Assembly.

As you can see, the AO switch set the location of the assembled program only. It did not set the location of the edit buffer or the symbol table.

If your ORG instruction does not allow enough memory for your program, you will get a BAD MEMORY error. The assembler cannot store your program beyond the top of RAM

Using /MO with /IM for Manual Origin

The /MO switch causes your program to be assembled at the address set by USRORG (plus the value set in your ORG instruction, if you use one). To set USRORG, use the editor's "origin". command.

Before setting USRORG, remove the ORG instruction from your program. Then, at the* prompt, type:

The editor shows you the current values for:

• FIRST - the first hexadecimal address available

- · LAST the last hexadecimal address available
- USRORG the current hexadecimal value of US-RORG. (On startup, USRORG is set to the top of RAM.)

It then prompts you for a new value for USRORG. If you want USRORG to remain the same, press (ENTER).

If you want to enter a new value, it must be between the FIRST address and LAST address. Otherwise, you will get a BAD MEMORY error.

EDTASM Systems: Set USRORG to \$6050:

USRORG=6050ENTER

EDTASMOV Systems: Set USRORG to \$3800:

USRORG=3800 ENTER

After setting USRORG, you can assemble the program at the USRORG address. Type:

A/IM/MOENTER

Your assembled program now starts at Address \$6050 or \$3800:

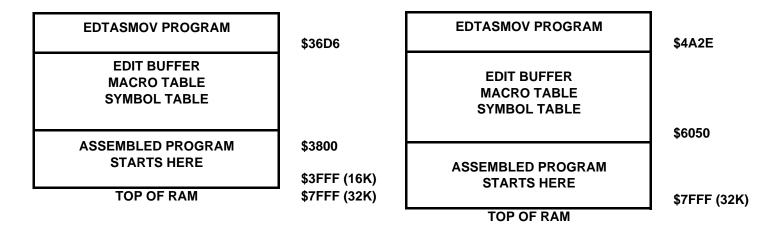

Figure 4. /MO In-Memory Assembly.

Disk Assembly

When you specify a filespec in the assembler command, the assembler saves the assembled program on disk. You can then load the program from one of these systems:

- DOS (to run as a stand-alone program)
- ZBUG (to debug with the stand-alone ZBUG program)
- BASIC (to call from a BASIC program)

The program originates at the address you specify in the ORG instruction.

What address you should use as the originating address depends upon which of the three systems you will be loading it into.

Assembling for DOS

Reference J shows the memory map that is in effect when DOS is loaded. As you can see, DOS consumes all the memory up to Address \$1200. This means you must originate the program after \$1200 or you will overwrite DOS.

In the sample program, reinsert the ORG \$1200 instruction:

50 ORG \$1200

and assemble it to disk by typing:

A SAMPLE /SRENTER

Note the /SR switch. You must use /SR when assembling to disk a program that you plan to load back into DOS. This puts the program in the format expected by DOS.

The assembler saves SAMPLE/BIN to disk with a starting address of \$1200. You can now load and execute SAMPLE/BIN from the DOS menu.

Assembling for Stand-Alone ZBUG (EDTASMOV Users)

If you plan to use the stand-alone ZBUG for debugging

your program, you need to save the program on disk so that you can load it into ZBUG.

Reference J also shows the memory map that is in effect when ZBUG is loaded. As you can see, you must use an originating address of at least \$3800 or you will- overwrite ZBUG. Change the ORG instruction to:

50 ORG \$3800

So that you can test this from ZBUG, without the program returning to BASIC, you need to change the ending of it. First, delete the CLR instruction in Line 170:

D17@ENTER

Then, change the JMP instruction in Line 180 to this:

180 SWI

After making the changes to the program, assemble it to disk by typing:

A SAMPLE/BUG /WSe

The assembler saves SAMPLE/BUG on disk with a starting address of \$3800. The /WS switch causes the assembler to save the symbol table also.

Hints On Assembly

- Use a symbol to label the beginning of your program.
- When doing an in-memory assembly on a program with an ORG instruction, you may want to use the /AO switch. Otherwise, the assembler will not use ORG as the program's originating address. It will use it to offset (add· to) the loading address.
- The /WE switch is an excellent debugging tool. Use it to detect assembly errors before debugging the program.
- If you would like to examine the edit buffer and symbol table after an in-memory assembly, use ZBUG to examine the appropriate memory locations.

Chapter 8/ Debugging the Program (ZBUG Commands — Part II)

ZBUG has some powerful tools for a trial run of your assembled program. You can use them to look at each register, every flag, and every memory address during every step of running the program.

Before reading any further, you might want to review the ZBUG commands you learned in *Chapter 5*. We will be using these commands here.

Preparing the Program for ZBUG

In this chapter, we'll use the sample program from *Chapter 2* to show how to test a program. How you load the program into ZBUG depends on whether you are using ED-TASM's ZBUG program or the stand-alone ZBUG program.

EDTASM ZBUG:

If you are using EDTASM, you can use EDTASM's ZBUG program.

- Load SAMPLE/ASM into EDTASM (if it's not already loaded).
- 2. So that your program will be in the same area of memory as ours, change the ORG instruction to:

50 ORG \$5800

 So that you can test the program properly from ZBUG (without the program returning to BASIC), you need to change the program's ending. First, delete the CLR instruction in Line 170:

D170 ENTER

Then, change the JMP instruction in Line 180 to this:

180 SWI

4. Assemble the program in memory using the /IM and /AO switches. At the* prompt, type:

A/IM/A0ENTER

5. Enter ZBUG. At the * prompt, type:

Z ENTER

When the # prompt appears, you're in ZBUG and can test the sample program.

Stand-Alone ZBUG:

If you are using EDTASMOV, you should use the Stand-Alone ZBUG.

- 1. Assemble SAMPLE/BUG to disk as instructed in the last chapter ("Assembling for Stand-Alone ZBUG").
- Return to DOS and execute the stand-alone ZBUG program:

EXECUTE A PROGRAM
PROGRAM NAME [ZBUG]/BIN

ZBUG loads and displays its # prompt.

3. Load SAMPLE/BUG, along with its symbol table, into ZBUG. Type:

LDS SAMPLE/BUGENTER

When the # prompt appears, you're ready to test the sample program with ZBUG.

Display Modes

In *Chapter 5*, we discussed four examination modes. ZBUG also has three display modes.

We'll examine each of these display modes from the mnemonic examination mode. If you're not in this mode, type MENTER to get into it.

Numeric Mode

Type:

N ENTER

and examine the memory addresses that contain your program: \$5800-\$5817 for EDTASM's ZBUG or \$3800 - \$3817 for Stand-Alone ZBUG.

In the numeric mode, you do not see any of the symbols in your program (BEGIN, START, SCREEN, WAIT, and DONE). All you see are numbers. For example, with EDTASM's ZBUG, Address \$580F shows the instruction BNE 580A rather than BNE SCREEN.

Symbolic Mode

From the command level, type:

SENTER

and examine your program again. ZBUG displays your entire program in terms of its symbols (BEGIN, START, SCREEN, WAIT, and DONE). Examine the memory address containing the BNE SCREEN instruction and type:

;

The semicolon causes ZBUG to display the operand (SCREEN) as a number (580A or 380A).

Half-Symbolic Mode

From the command level, type:

H ENTER

and examine the program. Now all the memory addresses (on the left) are shown as symbols, but the operands (on the right) are shown as numbers.

Using Symbols to Examine Memory

Since ZBUG understands symbols, you can use them in your commands. For example, with EDTASM's ZBUG, both these commands open the same memory address no matter which display mode you are in:

BEGIN/ 5800/ Both of these commands get ZBUG to display your entire program:

T BEGIN DONE T 5800 5817

You can print this same listing on your printer by substituting TH for T.

Executing the Program

You can run your program from ZBUG using the G (Go) command followed by the program's start address:

EDTASM ZBUG: Type either of the following:

GBEGINENTER
G5800 ENTER

Stand-Alone ZBUG: Type either of the following:

GBEGINENTER
G3800ENTER

The program executes, filling all of your screen with a pattern made up of F9 graphics characters. If you don't get this pattern, the program probably has a "bug." The rest of the chapter discusses program bugs.

After executing the program, ZBUG displays 8 BRK @ 5817, 8 BRK @ 3817, or 8 BRK @ DONE. This tells you the program stopped executing at the SWI instruction located at Address DONE. ZBUG interprets your closing SWI instruction as the eighth or final "breakpoint" (discussed below).

Setting Breakpoints

If your program doesn't work properly, you might find it easier to debug it if you break it up into small units and run each unit separately. From the command level, type X followed by the address where you want execution to break.

We'll set a breakpoint at the first address that contains the symbol SCREEN: \$580A for EDTASM's ZBUG or 380A for Stand-Alone ZBUG.

EDTASM ZBUG: Type either of the following:

XSCREENENTER X580 ENTER

Stand-Alone ZBUG: Type either of the following:

XSCREENENTER X380AENTER

Now type GBEGINENTER to execute the program. Each time execution breaks, type:

CENTER

to continue. A graphics character appears on the screen each time ZBUG executes the SCREEN loop. (The characters appear to be in different positions because of scrolling. You will not see the first 32 characters because they scroll off the screen.)

Type:

ENTER

to display all the breakpoints you have set. (You may set up to eight breakpoints numbered O through 7.)

Type:

C10 ENTER

and the tenth time ZBUG encounters that breakpoint, it halts execution.

Type:

YENTER

This is the command to "yank" (delete) all breakpoints. You can also delete a specific breakpoint. For example:

Y Ø ENTER

This deletes the first breakpoint (Breakpoint 0).

You may not set a breakpoint in a ROM routine. If you set a breakpoint at the point where you are calling a ROM routine, the C command will not let you continue.

Examining Registers and Flags

Type:

ENTER

What you see are the contents of every register during this stage of program execution. (See Chapter 10 for definition of all the 6809 registers and flags.)

Look at Register CC (the Condition Code). Notice the letters to the right of it. These are the flags that are set in Register CC. The E, for example, means the E flag is set.

Type:

ΧZ

and ZBUG displays only the contents of Register X. You can change this in the same way you change the contents of memory. Type:

Ø ENTER

and the Register X now contains a zero.

Stepping Through the Program

BEGIN, Note the comma!

LDA #\$F9 is the next instruction to be executed. The first instruction, JMP START, has just been executed. To see the next instruction, type:

Simply a comma

Now, LOA #\$F9 has been executed and LOX #\$500 is the next. Type:

ENTER

and you'll see this instruction has loaded Register A with \$F9.

Use the comma and R command to continue singlestepping through the program examining the registers at will. If you manage to reach the JSR [\$AOOO] instruction, ZBUG prints:

CAN'T CONTINUE

ZBUG cannot single-step through a ROM routine or through some of the DOS routines.

Transferring a Block of Memory

EDTASM ZBUG: Type:

U 5800 5000 6 ENTER

Stand-Alone ZBUG: Type:

U 3800 3850 6ENTER

Now the first six bytes of your program have been copied to memory addresses beginning at 5000 or 3850

Saving Memory to Disk

To save a block of memory from ZBUG, including the symbol table, type:

EDTASM ZBUG: PS TEST/BUG 5800

5817 5800 ENTER

Stand-Alone ZBUG: PS TEST /BUG 3800

3817 3800 ENTER

This saves your program on disk, beginning at Address 5800 (or 3800) and ending at Address 5817 (or 3817). The last address is where your program begins execution when you load it back into memory. In this case, this

address is the same as the start address.

To load TEST/BUG and its symbol table back into ZBUG, type:

LDS TEST/BUGENTER

Hints on Debugging

- Don't expect your first program to work the first time. Have patience. Most new programs have bugs. Debugging is a fact of life for all 'programmers, not just beginners.
- Be sure to make a copy of what you have in the edit buffer before executing the program. The edit buffer is not protected from machine language programs.
 ZBUG has a built-in calculator that performs arithmetic, relational, and logical operations. Also, it lets you use three different numbering systems, ASCII characters, and symbols.

Chapter 9/ Using the ZBUG Calculator (ZBUG Commands — Part III)

This chapter contains many examples of how to use the calculator. Some of these examples use the same assembled program that we used in the last chapter.

Stand-Alone ZBUG: Some of the memory addresses we use in the examples are too high for your system. Subtract \$1000 from all the hexadecimal addresses and 4096 from all the decimal numbers.

Numbering System Modes

ZBUG recognizes numbers in three numbering systems: hexadecimal (Base 16), decimal (Base 10), and octal (Base 8).

Output Mode

The output mode determines which numbering system ZBUG uses to output (display) numbers. From the ZBUG command level, type:

010 ENTER

Examine memory. The T at the end of each number stands for Base 10. Type:

Ø8ENTER

Examine memory. The Q at the end of each number stands for Base 8. Type:

016 ENTER

You're now back in Base 16, the default output mode.

Input Mode

You can change input modes in the same way you change output modes. For example, type:

I 1 Ø ENTER

Now, ZBUG interprets any number you input as a Base 10 number. For example, if you are in this mode and type:

T 49152 49162ENTER

ZSBUG shows you memory addresses 49152 (Base 10) through 49162 (Base 10). Note that what is printed on the screen is determined by the output mode, not the input mode.

You can use these special characters to "override" your input mode:

BASE	BEFORE NUMBER	AFTER NUMBER
Base 10	&	T
Base 16	\$	Н
Base 8	@	Q

Table 1. Special Input Mode Characters

For example, while still in the 110 mode, type:

T 49152 \$C010 ENTER

The "\$" overrides the 110 mode. ZBUG, therefore, interprets C010 as a hexadecimal number. As another example, get into the 116 mode and type:

T 49152T C010 ENTER

Here, the "T" overrides the 116 mode. ZBUG interprets 49152 as decimal.

Operations

ZBUG performs many kinds of operations for you. For example, type:

and ZBUG goes to memory address C019 (Base 16), the sum of COOO (Base 16) and 25 (Base 10). If you simply want ZBUG to print the results of this calculation, type:

On the following pages, we'll use the terms "operands," "operators," and "operation." An operation is any calculation you want ZBUG to solve. In this operation:

$$1 + 2 =$$

"1" and "2" are the operands. "+" is the operator.

Operands

You may use any of these as operands:.

- 1. ASCII characters
- 2. Symbols
- 3. Numbers (in either Base 8, 1 o, or 16) Please note that ZBUG recognizes integers (whole numbers) only

Examples (Get into the 016 mode):

prints 41, the ASCII hexadecimal code for "A".

prints the START address of the sample program. (It will print UNDEFINDED SYMBOL if you don't have the sample program assembled in memory.)

prints the hexadecimal equivalent of octal 15.

If you want your results printed in a different numbering

system, use a different output mode. For example, get into the 010 mode and try the above examples again.

Operators

You may use arithmetic, relational, or logical operators. (Get into the 016 mode for the following examples.)

Arithmetic Operators

Addition +
Subtraction Multiplication *
Division .DIV.
Modulus .MOD.
Positive +
Negative -

Examples:

prints the length of the sample program (not including the SWI at the end).

prints 4. (ZBUG can divide integers only.)

prints 1, the remainder of 9 divided by 2.

$$1 - 2 =$$

prints 0FFFF,65535T, or 177777Q, depending on which output mode you are in. ZBUG does not use negative numbers. Instead, it uses a "number circle" which operates on modulus 10000 (hexadecimal):

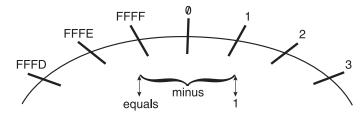

Figure 5. Number Circle Illustration of Memory

To understand this number circle, you can use the clock as an analogy. A clock operates on modulus 12 in tile same way the ZBUG operates on modulus 10000. Therefore, on a clock, 1:00 minus 2 equals 11:00:

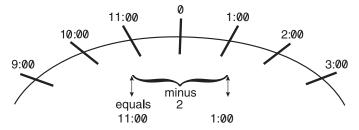

Figure 6. Number Circle Illustration of Clock.

Relational Operators

Equal to .EQU. Not Equal to .NEQ.

These operators determine whether a relationship is true or false.

Examples:

prints 0FFFF, since the relationship is true. (ZBUG prints 65535T in the 010 mode or 177777Q in the 08 mode.)

prints 0, since the relationship is false.

Logical Operators

Shift	<
LogicalAND	.AND.
InclusiveOR	.OR.
ExclusiveOR	.XOR.
Complement	.NOT.

Logical operators perform bit manipulation on binary numbers. To understand bit manipulation, see the

6809 assembly language book we referred to in the introduction.

Examples:

shifts 1 O two bits to the left to equal 40. The 6809 SL instruction also performs this operation.

shifts 10 two bits to the right to equal 4. The 6809 ASR instruction also performs this operation.

prints 3, the exclusive or of 6 and 5. The 6809 EOR instruction also performs this operation.

Complex Operations

ZBUG calculates complex operations in this order:

You may use parentheses to change this order.

Examples:

The division is performed first.

The addition is performed first.

The multiplication is performed first.

SECTION III

ASSEMBLY LANGUAGE

SECTION III

ASSEMBLY LANGUAGE

This section gives details on the Disk EDTASM assmbly language. It does not explain the 6809 mnemonics, however, since there are many books available on the 6809.

To learn about 6809 mnemonics, read one of the books listed in "About This Manual." if you need more technical information on the 6809 read:

MC68090MC6809E 8-Bit Microprocessor Programming Manual Motorola, Inc.

Chapter 10/ Writing the Program

Chapter 3 gives a general description of assembly language instructions. This chapter describes them in detail.

The 6809 Registers

The 6809 contains nine temporary storage areas that you may use in your program:

REGISTER	SIZE	DESCRIPTION
Α	1 byte	Accumulator
В	1 byte	Accumulator
D	2 bytes	Accumulator
		(a combination
		of A and B)
DP	1 byte	Direct Page
CC	1 byte	Condition Code
PC	2 bytes	Program Counter
X	2 bytes	Index
Υ	2 bytes	Index
U	2 bytes	Stack Pointer
S	2 bytes	Stack Pointer

Table 2. 6809 Registers

Registers A and **B** can manipulate data and perform arithmetic calculations. They each hold one byte of data. If you like, you can address them as D, a single 2-byte register.

Register DP is for direct addressing. It stores the most significant byte of an address. This lets the processor directly access an address with the single, least significant byte.

Registers X and **Y** can each hold two bytes of data. They are mainly for indexed addressing.

Register PC stores the address of the next instruction to be executed.

Registers U and **S** each hold a 2-byte address that points to an entire "stack" of memory. This address is the top of the stack + 1. For example, if Register U contains 0155, the stack begins with Address 154 and continues downwards.

The processor automatically points Register S to a stack of memory during subroutine calls and interrupts. Register U is solely for your own use. You can access either stack with the PSH and PUL mnemonics or with indexed addressing.

Register CC is for testing conditions and setting interrupts. It consists of eight "flags." Many mnemonics "set" or "clear" one or more of these flags. Others test to see if a certain flag is set or clear.

This is the meaning of each flag, if set:

C (Carry), Bit 0 — an 8-bit arithmetic operation caused a carry or borrow from the most significant bit.

V (Overflow), Bit 1 — an arithmetic operation caused a signed overflow.

Z (**Zero**), **Bit 2** — the result of the previous operation is zero.

N (Negative), Bit 3 — the result of the previous operation is a negative number.

I (Interrupt Request Mask), Bit 4 — any requests for interrupts are disabled.

H (Half Carry), Bit 5 — an 8-bit addition operation caused a carry from Bit 3.

F (Fast Interrupt Request Mask), Bit 6 — any requests for fast interrupts are disabled.

E (Entire Flag), Bit 7 — all the registers were stacked during the last interrupt stacking operation. (If not set, only Registers PC and CC were stacked.)

Assembly Language Fields

You may use four fields in an assembly language instruction:

Assembly Language Fields

You may use four fields in an assembly language instruction:

START LOA #\$F9 GETS CHAR

START is the label. LOA is the command. #\$F9 + 1 is the operand. GETS CHAR is the comment.

The comment is solely for your convenience. The assembler ignores it.

The Label

You can use a symbol in the label field to define a memory address or data. The above instruction uses START to define its memory address.

Once the address is defined, you can use START as an operand in other instructions. For example:

BNE START

branches to the memory address defined by START.

The assembler stores all the symbols, with the addresses or data they define, in a "symbol table," rather than as part of the "executable program." The symbol can be up to six characters.

The Command

The command can be either a pseudo op or a mnemonic.

Pseudo ops are commands to the assembler. The assembler does not translate them into opcodes and does not store them with the executable program. For example:

NAME EQU \$43

defines the symbol NAME as \$43. The assembler stores this in its symbol table.

ORG \$3000

tells the assembler to begin the executable program at Address \$3000.

SYMBOL FCB \$6

stores 6 in the current memory address and labels this address SYMBOL. The assembler stores this information in its symbol table.

Mnemonics are commands to the processor. The

assembler translates them into opcodes and stores them with the executable program. For example:

CLRA

tells the processor to clear Register A. The assembler assembles this into opcode number \$4F and stores it with the executable program.

The next chapter shows how to use pseudo ops. Reference L lists the 6809 mnemonics.

The Operand

The operand is either a memory address or data. For example:

LDD #3000+COUNT

loads Register 0 with \$3000 plus the value of COUNT. The operand, #\$3000 + COUNT, specifies a data constant.

The assembler stores the operand with its opcode. Both are stored with the executable program.

Operators

The plus sign (+) in the above operand (#3000 + COUNT) is called an operator.

You can use any of the operators described in Chapter 9, "Using the ZBUG Calculator," as part of the operand.

Addressing Modes

The above example uses the # sign to tell the assembler and the processor that \$3000 is data. When you omit the # sign, they interpret \$3000 in a different "addressing mode."

Example:

LDD \$3000

tells the assembler and processor that \$3000 is an address. The processor loads O with the data contained in Address \$3000 and \$3001.

Each of the 6809 mnemonics lets you use one to six addressing modes. These addressing modes tell you:

- If the processor requires an operand to execute the opcode
- How the assembler and processor will interpret the operand

1. Inherent Addressing

There is no operand, since the instruction doesn't require one. For example:

SWI

interrupts software. No operand is required.

CLRA

clears Register A. Again, no operand is required. Register A is part of the instruction.

2. Immediate Addressing

The operand is data. You must use the# sign to specify this mode. For example:

ADDA

#\$30

adds the value \$30 to the contents of Register A.

DATA

EQU

\$8004

LDX

#DATA

loads the value \$8004 into Register X.

CMPX

#\$1234

compares the contents of Register X with the value 1234.

3. Extended Addressing

The operand is an address. This is the default mode of all operands.

(Exception: If the first byte of the operand is identical to the direct page, which is 00 on startup, it is directly addressed. This is an automatic function of the assembler and the processor. You need not be concerned with it if you're a beginner.)

For example:

JSR

#\$1234

jumps to Address \$1234.

SPOT

EOU

\$1234

STA

SPOT

stores the contents of Register A in Address \$1234.

If the instruction calls for data, the operand contains the address where the data is stored.

LOA

\$1234

does not load Register A with \$1234. The processor loads A with whatever data is in Address \$1234. If \$06 is

stored in Address \$1234, Register A is loaded with \$06.

ADDA

\$1234

adds whatever data is stored in Address \$1234 to the contents of Register A.

LDD

\$1234

loads D, a 2-byte register, with the data stored in memory addresses \$1234 and \$1235.

You can use the > sign, which is the sign for extended addressing, to force this mode. (See "Direct Addressing.")

Extended Indirect Addressing.

The operand is the address of an address. This is a variation of the extended addressing mode. The [] signs specify it. (Use SHIFT) to produce the [sign and SHIFT) to produce the] sign.)

In understanding this mode, think of a treasure hunt game. The first instruction is "Look in the clock." The clock contains the second instruction, "Look in the refrigerator. "

Examples:

JSR

[\$1234]

jumps to the address contained in Addresses \$1234 and \$1235. If \$1234 contains \$06 and \$1235 contains \$11, the effective address is \$0611. The program jumps to \$0611.

SPOT

EQU

\$1234

STA

[SPOT]

stores the contents of Register A in the address contained in Addresses \$1234 and \$1235.

LDD

[\$1234]

loads D with the data stored in the address that is stored in Addresses \$1234 and \$1235.

This is a good mode of addressing to use when calling ROM . routines. For example, the entry address of the POLCAT routine is contained in Address \$A000. Therefore, you can call it with these instructions:

POLCAT

EQU

\$A000

JSR

[POLCAT]

If a new version of ROM puts the entry point in a different address, your program still works without changes.

4. Indexed Addressing

The operand is an index register which points to an

address. The index register can be any of the 2-byte registers, including PC. You can augment it with:

- · A constant or register offset
- An auto-increment or auto-decrement of 1 or 2

The comma(,) indicates indexed addressing. As an example, load X, a 2-byte register, with \$1234:

You can now access Address \$1234 through indexed addressing. This instruction:

stores the contents of A in Address \$1234

stores the contents of A in Address \$1237, which is \$1234 + 3. (The number 3 is a constant offset.)

stores the contents of A in Address \$1238, which is \$1234 + SYMBOL. (SYMBOL is a constant offset.)

stores the contents of A in Address \$1239 which is \$1234 + the contents of B. (B is a register offset. You can use either of the accumulator registers as a register offset.)

This instruction does two tasks: (1) stores A's contents in Address \$1234 (the contents of X) and then \cdot (2) increments

X's contents by one, so that X contains \$1235.

(1) stores A's contents in Address \$1235 (the current contents of X) and then (2) increments X's contents by two to equal \$1237.

(1) decrements the current contents of X by two to equal \$1235 (\$1237 - 2) and then (2) stores A's contents in Address \$1235.

As we said above, you can use PC as an index register. In this form of addressing, called program counter relative, the offset is interpreted differently. For example:

LDA SYMBOL,PCR

While assembling the program, the assembler subtracts the contents of Register PC from the offset:

While running the program, the processor adds the contents of Register PC to the offset. This causes A to be loaded with SYMBOL.

This seems to be the same as extended addressing. But, by using program counter relative adressing, you can relocate the program without having to reassemble it.

Indexed Indirect Addressing.

The operand is an *index register* which points to the *address* of an *address*. This is a variation of indexed addressing.

For example, assume that:

- Register X contains \$1234
- Address \$1234 contains \$11
- Address \$1235 contains \$23
- Address \$1123 contains \$64

This instruction:

loads A with 64. (Register X points to the addresses of the address. This address is storing 6, the required data.)

stores the contents of A in Address \$1123. (Register X points to the addresses, \$1234 and \$1235, of the effective address, \$1123.)

5. Relative Addressing

The assembler interprets the operand as a *relative address*. There is no sign to indicate this mode. The assembler automatically uses it for all branching instructions.

For example, if this instruction is located at Address \$0580:

The assembler converts \$0585 to a relative branch of + 3 (0585-0582).

This mode is invisible to you unless you get a BYTE OVERFLOW error, which we discuss below. Because the processor uses this mode, you can relocate your

program in memory without changing any of the branching instructions.

The BYTE OVERFLOW error means that the relative branch is outside the range of -128 to + 127. You must use a long branching instruction instead. For example:

LBRA

\$0600

allows a relative branching range of -32768 to + 32767.

6. Direct Addressing

In this mode, the operand is *half of an address*. The other half of the address is in Register DP:

ADDRESS

DP REGISTER = (most significant byte)

OPERAND (least significant byte)

Figure 7. Direct Addressing

The assembler and the processor use this mode automatically whenever they approach an operand whose first byte is what they assume to be a "direct page" (the contents of Register DP). Until you change the direct page, the assembler and the processor assume it is 00.

For example, both of these instructions:

JSR

\$0015

JSR

\$15

cause a jump to Address \$0015. In both cases, the assembler uses only 15 as the operand, not 00. When the processor executes them, it gets the 00 portion from Register DP and combines it with \$15. (On startup, DP contains 0, as do all the other registers.)

Because of direct addressing, all operands beginning with 00, the direct page, consume less room in memory

and run quicker. If most of your operands begin with \$12, you might want to make \$12 the direct page.

To do this, you first need to tell the assembler what you are doing, by putting a SETDP pseudo-operation in your program:

SETDP

\$12

This tells the assembler to drop the \$12 from all operands that begin with \$12. That is, the assembler assembles the operand "1234" as simply "34".

Then, you must load Register DP with \$12. Since you can use LD only with the accumulator registers, you have to load DP in a round-about manner:

LDB

#\$12

TFR

B,DP

Now the direct page is \$12, rather than 00. The processor executes all operands that begin with \$12 (rather than 00) in an efficient, direct manner.

The assembler uses direct addressing on all operands whose first byte is the same as the direct page. You can denote direct addressing with the < sign if you want to document or be sure that direct addressing is being used.

For example, if the direct page is \$12:

JSR

<\$15

jumps to Address \$1215. This instruction documents that the processor uses direct addressing.

Similarly, you might want to use the > sign to force extended addressing. For example:

ISR

>\$1215

jumps to Address \$1215. The assembler and processor use both bytes of the operand.

To learn more about 6809 addressing modes, read one of the books listed at the beginning of this manual.

Chapter 11/ Using Psuedo Ops

As discussed earlier, pseudo ops direct the assembler. You can use them to:

- Control where the program is assembled
- Define symbols
- Insert data into the program
- · Change the assembly listing
- Do a "conditional" assembly
- Include another source file in your program

Pseudo ops are unique to the assembler you are using. Other 6809 assemblers may not recognize the Disk ED-TASM pseudo ops.

The Disk EDTASM pseudo ops make it easier for you to program. This chapter shows how to use pseudo ops.

Controlling Where the Program is Assembled

The Disk EDTASM has two pseudo ops that control where the program is assembled:

- ORG, sets the first location
- END, ends the assembly

ORG

ORG expression

Tells the assembler to begin assembling the program at expression. Example:

ORG \$1800

tells the assembler to start assembling the program at Address \$1800.

You can put more than one ORG command in a pro-

gram. When the assembler arrives at the new ORG, it begins assembling at the new expression.

END

END expression

Tells the assembler to quit assembling the program. The *expression* option lets you store the program's start address. Use END as the last instruction in all your assembly language programs.

Example:

DATA START	ORG FCC LDA	\$1800 'This DATA	is	some	data'
	END	старт			

The END pseudo op quits the assembly and stores the program's entry address (the value of START) on disk. When you load the program, the processor knows to start executing at START (the LOA instruction) rather than at DATA (the FCC instruction).

FCC is a pseudo op explained later in this chapter.

Defining Symbols

Symbols make it easy to write a program and also make the program easy to read and revise. The Disk EDTASM has two pseudo ops for defining symbols:

- EQU, for defining a constant value
- SET, for defining a variable value

EQU

symbol EQU expression

Equates symbol to expression. Examples:

CHAR EOU

\$F9

\$500

equates CHAR to \$F9.

SCREEN EQU

LDX #SCREEN

equates SCREEN to \$500. The next instruction loads X with \$500.

EQU helps set the values of constants. You can use it anywhere in your program.

SET

symbol SET expression

Sets symbol equal to expression. You can use SET to reset the symbol elsewhere in the program. Example:

SYMBOL SET 25

sets SYMBOL equal to 25. Later in the program, you can reset SYMBOL.

SYMBOL SET SYMBOL+COUNT

now SYMBOL equals 25 +COUNT.

Inserting Data into Your Program

The Disk EDTASM has four pseudo ops that make it simple for you to reserve memory and insert data in your program:

- RMB, for reserving areas of memory for data
- FCB, for inserting one byte of data in memory
- FOB, for inserting two bytes of data in memory
- FCC, for inserting a string of data in memory

Remember that the processor cannot "execute" a block of data in your program. If you use these pseudo ops:

- Use them at the end of your program (just before the END instruction), or
- Precede them with an instruction that jumps or branches to the next "executable" instruction.

RMB

symbol RMB expression

Reserves expression bytes of memory for data. Example:

BUFFER

RMB

256

reserves 256 bytes for data, starting at Address BUFFER.

DATA

RMB

B+SYMBOL

reserves 6 +SYMBOL bytes for data beginning at Address DATA.

FCB

symbol FCB expression

Stores a 1-byte expression in memory at the current address. The symbol is optional.

Examples:

DATA

FCB \$33

stores \$33 in Address DATA.

FACTOR FCB NUM/2

LDA FACTOR

stores NUM/2 in Address FACTOR, then, loads NUM/2 into Register A.

FDB

symbol FDB expression

Stores a 2-byte expression in memory starting at the current address. The symbol is optional. Example:

DATA

FDB

\$3322

stores \$3322 in Address DATA and DATA + 1.

FCC

symbol FCC delimiter string delimiter

Stores an ASCII string in memory, beginning at the current address. The symbol is optional. The delimiter can be any character.

Examples:

TABLE

FCC /THIS IS A STRING/

stores the ASCII codes for THIS IS A STRING in memory locations, beginning with TABLE.

NAME	FCC FCB	'Dylan' \$0D
	LDB	#NAME
INIT	LDA	NAME
	=	
	INCB	
	CMPA	NAME
	BNE	TINI

The first instruction stores "Dylan" in the five memory addresses beginning with NAME. The next instructions process this data.

Changing the Assembly Listing

You can use three pseudo ops to change the listing the assembler prints for you:

- TITLE, inserts a title at the top of each listing page
- PAGE, ejects the listing to the next page
- OPT, turns on or off the switches that determine how the assembler lists "macros" (Macros are discussed in the next chapter.)

TITLE string

Tells the assembler to print the first 32 characters of the string at the top of each assembly listing page. Example:

TITLE Budget Program

causes the assembler to print Budget Program as the title of each page in the assembly listing.

PAGE

Starts a new page if the assembly listing is being printed on the line printer. Example:

PAGE

tells the assembler to eject the listing to the next page.

OPT

OPT switch, switch, ...

Causes the assembler to use the specified switches when printing its listing. You can specify these switches with OPT:

MC List macro calls (default)
NOMC Do not list macro calls

MD	List macro definitions (default)
NOMD	Do not list macro definitions
MEX	List macro expansions
NOMEX	Do not list macro expansions (default)
L	Turn on the listing (default)
NOL	Turn off the listing
Example:	
OPT	MEX

Causes the assembler to list the macro expansions in its listing. (Macros are discussed in the next chapter.)

Conditional Assembly

You may want to execute a certain section of your program only if a certain condition is true. The Disk EDTASM lets you set up a "conditional" section of your program, using these two pseudo ops:

COND

COND condition expression

Assembles the following instructions only if the expression is true (non-zero). If not true (zero), the assembler goes to the instruction that immediately follows the ENDC instruction.

Only these operators are recognized in a condition expression: +,-,/,*.See ENDC below for an example.

ENDC

ENDC

Ends a conditional assembly, initiated by COND.

Examples:

COND SYMBOL
.
ENDC

assembles the lines between COND SYMBOL and ENDC only if SYMBOL is not equal to zero.

COND VALUE2-VALUE1
.
.
ENDC

assembles the lines between VALUE2-VALUE1 only if VALUE2-VALUE1 are not equal (which causes the result to be a non-zero value).

Including Other Source Files

To let you load another source file and include it in your program, the Disk EDTASM offers an INCLUDE pseudo op.

INCLUDE

INCLUDE *filespec*

Inserts filespec, a file of source assembly language instructions, at the point where INCLUDE appears in the

program. The assembler assembles the entire included file before assembling the next instruction.

Example:

INCLUDE ROUTINE/SRC

inserts and assembles ROUTINE/SAC, a source file, before assembling the next instruction.

INCLUDE SUB1/SRC INCLUDE SUB2/SRC

inserts and assembles SUB1, then inserts and assembles SUB2, then proceeds with the next instruction.

Chapter 12/ Using Macros

A macro is like a subroutine. It lets you call an entire group of instructions with a single program line. This helps when you want to use the same group of instructions many times in the program.

This chapter first tells how to use a macro. It then gives guidelines on the format of a macro.

How to Use a Macro

To use a macro, you must first define it. For example, you could define the entire sample program (from Chapter 2) as a macro named GRAPH.

After defining the macro, you can use its name the same way you use a mnemonic. Whenever the assembler encounters the macro's name, it expands it into the defined instructions.

Defining a Macro

To define a macro, you need to:

- Use MACRO (a pseudo op) to begin the macro definition and assign it a name.
- Use source instructions to define the macro.
- Use ENDM (a pseudo op) to end the macro definition.

This is an example of the sample program converted into a macro definition:

00030	GRAPH	MACRO	
00100		LOA	#\$F9
00110		LOX	#\$400
00120	∖,Α	STA	,X+
00130		CMPX	#\$600
00140		BNE	A
00150	∖,₿	JSR	[\$A000]
00160		BEQ	∖,B
00180		ENDM	

Line 30 names the macro as GRAPH, lines 50-160 define the macro, and line 180 ends the macro definition.

Notice the names of the symbols within the macro definition: \.A and \ .B. If you do not use this format for naming symbols, you'll get a MULTIPLY DEFINED SYMBOL error when you call the macro more than once. (More on this later.)

Insert the above program using SHIFT CLEAR to generate the backslash character (\). Save the program on disk as MACRO1 and then delete it.

```
WD MACRO 1 ENTER
D#:* ENTER
```

Calling a Macro

To call a macro, simply use the macro name as if it were a mnemonic. For example, this sample program calls GRAPH and then ends:

00110		ORG	\$1200
00120	BEGIN	JMP	START
00130		FDB	DONE-BEGIN
00140	START	*	
00150		INCLUDE	MACR01/ASM
00160	GRAPH		
00170	CLR	\$71	
00180	JMP	[\$FFFE]	
00190	DONE	*	
00200	END		

Line 150 loads MACRO1, the file containing the definition of GRAPH, and includes it in the source program. Line 160 calls the GRAPH macro.

To see how the assembler expands the GRAPHIC macro, insert this line:

0013	Ε,	M	PT	MEX
4.4.4.4			i i	111

and assemble the program. The assembler listing shows how the assembler expands GRAPH into its defined instructions.

Note that the assembler has replaced \.A with A0000 and \.B with 80000. The zeroes indicate that this is the first expansion of the symbols in GRAPH. (In this case, this is the only expansion.)

Passing Values to a Macro

A convenient way to use a macro is to pass values to it. You can use a macro many times in your program, passing different values to it each time.

This is a definition of the GRAPH macro, slightly modified so that you can pass two values to it. Insert this program, save it as MACR02 and then delete it.

00030	GRAPH2	MACRO	
00100		LDA	\0
00110		LDX	$\setminus 1$
00120	∖. A	STA	1 X +
00130		CMPX	#\$600
00140		BNE	∖,A
00150	∖,₿	JSR	[\$A000]
00160		BEQ	∖,B
00190		ENDM	

The \0 and \1 are dummy values. The assembler replaces these numbers with the values you specify when you call GRAPH.

The following program calls GRAPH2 three times. Each time it passes two different sets of values:

00100		ORG	\$1200
00110	BEGIN	JMP	START
00120		FOB	DONE-BEGIN
00130	START	*	
00140		OPT	MEX
00150		INCLUDE	MACR02/ASM
00180		GRAPH2	#\$F81#\$400
00170		GRAPH2	#\$F81#\$450
00180		GRAPH2	#\$F71#\$500
00180		CLR	\$71
00200		JMP	[\$FFFE]
00210	DONE	*	
00220		END	

When the assembler expands the macro, it replaces the dummy values with the values passed by the macro call. For example, the second time GRAPH2 is called, the assembler replaces \0 with #\$F8 and replaces \1 with #\$450.

Assemble the above program. Note that each time the assembler expands GRAPH2, it replaces the \.A and \.B symbols with different symbol names: First A0000 and B0000, then A0001 and B0001, and finally A0002 and B0002.

If the assembler used the same symbol names in each expansion, it would be forced to assign different value to the symbols in each expansion. You would get a MULTIPLY DEFINED SYMBOL error.

Also, note the assembler has inserted an additional symbol, NARG, in the symbol table. NARG is always set to the number of values passed in the most recent macro call.

In the sample program, the symbol table shows that NARG is set to "2" at the end of the assembly. This shows that there were two values passed to GRAPH2 the last time it was called.

You might want to use NARG as a variable in your program. For example, you could conditionally assemble parts of a macro definition based on the current value of NARG.

To see the program run, assemble it to disk, press a key three times to see different graphics and then end the program.

Format of Macros

The remainder of this chapter gives details on the format to use in a macro definition and macro call.

Macro Definition

Beginning the Definition

Use this format for beginning the macro definition and assigning it a name:

symbol MACRO

symbol is the name of the macro. It is, of course, required.

Using Symbols in the Definition

Use this format to name any symbols you use within a macro definition:

\.C

c is an alpha character (A-Z). When the assembler expands the macro, it replaces \.c with:

cnnnn

nnnn is a 4-digit hexadecimal number that the assembler increments each time the assembler expands the macro.

For example, if you use the symbol \.M in the macro definition and you call the macro 10 times, the assembler replaces \.M with these symbol names:

1st expansion M0001 2nd expansion M0002

10th expansion M000A

You must use this symbol-name format when calling a macro more than once. Otherwise, you get MULTIPLY DEFINED SYMBOL errors.

Using Dummy Values in the Definition

Use this format for specifying dummy values within a macro definition:

\n

n is an alphanumeric character (0-9,A-Z). The assembler replaces this dummy value with a corresponding value in the macro call line:

\0 is replaced with the 1st value \1 is replaced with the 2nd value

.

\9 is replaced with the 10th value \A is replaced with the 11th value

•

\Z is replaced with the 36th value

For example, this line in a macro definition:

specifies \B as a dummy value. The assembler replaces \B with the 12th value in the macro call line. If the macro call line is:

ADD NUMØ, NUM1, NUM2, NUM3, NUM4, NUM5, NUM6, NUM7, NUM8, NUM9, NUMA, NUMB

the assembler replaces \B with NUMB.

You do not need to assign macro call values to dummy values in consecutive order. For example:

	GRAPHX	#\$F9,#\$400,#\$600
GRAPHX	MACRO	
	LDX	$\searrow 1$
	LDY	\2
	LDA	∖ Ø
	LDB	∖ Ø
	ENDM	

Here, the assembler replaces dummy value \1 with#\$400, replaces dummy value \2 with #\$600, and, in two lines, replaces dummy value \0 with #\$F9. Note that you can pass a value to a macro more than once, as this example does with #\$F9.

If there are more dummy values than values in a macro call, a byte overflow error results.

If there are more values than dummy values in a macro call, the extra values are ignored.

Be sure not to enclose dummy values in quotes. If you do this, the assembler treats them as ordinary characters.

Ending the Macro Definition

Use this format for ending the macro definition:

ENDM

You may not use a symbol to label this line. If you do so, you get a MISSING END STATEMENT error at the end of the assembly listing.

Macro Call

Use this format when passing values to a macro in a macro call line:

macro call string 1, string 2, ...

macro call is the name of the macro.

string(s) is the value being passed to the macro. It can be 1 to 16 characters (any extra characters are ignored).

Each string, except the last, must be separated by a comma. The last string must be terminated by a comma, space, carriage return, or tab.

Each string may contain any characters except a carriage return. If a string contains a comma, space, tab, or left parenthesis, you must enclose it in parentheses. For example, in this macro call:

the assembler interprets ABC,DEF as a single string. However, in this call:

PRINT ABC, DEF

the assembler interprets ABC as one string and DEF as another.

Hints on Macros

 Remember to define a macro before calling it. If you call a macro without defining it, you get a BAD OP-CODE error.

12 / USING MACROS

- We recommend storing all macro definitions in a file and then using INCLUDE to insert them into your main program.
- Do not use a mnemonic or pseudo op as a macro name. This causes the assembler to redefine the mnemonic or pseudo op according to the macro definition.
- If the macro definition has an error, you will not discover
- the error until you call the macro. The assembler waits until you call the macro before it assembles it.
- You cannot "nest" macro definitions. That is, one macro definition cannot call another.
- Using the same macro more than once uses a large amount of memory. Expand a large macro only once.
 When you want to use it again, call it as a subroutine.

SECTION IV

ROM AND DOS ROUTINES

SECTION IV

ROM AND DOS ROUTINES

In an assembly language program, the simplest way to use the I/O devices is with ROM and DOS routine. This section shows how.

Complete lists of the ROM routines and DOS routines are in the reference section.

Chapter 13/ Using the Keyboard and Video Display (ROM Routines)

The Color Computer uses its own machine-code routines to access the screen, keyboard, and tape. These routines are built into the computer's ROM. You can use the same routines in your own program.

Appendix F lists each ROM routine and the ROM address that points to it. This chapter uses two of these routines, POLCAT and CHROUT, as samples in showing the steps for using ROM routines.

Steps for Calling ROM Routines

We recommend these steps for calling a ROM routine:

- 1. Equate the routine's address to its name. This lets you refer to the routine by its name rather than its address, making your program easier to read and revise.
- 2. Set up any entry conditions required by the routine. This lets you pass data to the routine.
- Preserve the contents of the registers. Since many routines change the contents of the registers, you might want to store the registers' contents temporarily before jumping to the routine.
- Call the ROM routine, using the indirect addressing mode
- 5. Use any exit conditions that the routine passes back to your program.
- 6. Restore the contents of the registers (if you temporarily preserved them in Step 3).

Sample 1 Keyboard Input with POLCAT

POLCAT "polls" the keyboard to see if you press a key. If you do not, POLCAT sets Bit Z.

If you do press a key, POLCAT:

(1) Clears Bit Z of Register CC and (2) Loads Register A with the key's ASCII code.

This short program uses POLCAT to poll the keyboard. When you press a key, the program ends:

	ORG	\$1200
BEGIN	JMP	START
	FOB	DONE-BEGIN
POLCAT	EQU	\$A000
START	PSHS	DP,CC,X,Y,U
WAIT	JSR	[POLCAT]
	BEQ	WAIT
	PULS	DP,CC,X,Y,U
	CLR	\$71
	JMP	[\$FFFE]
DONE	*	
	END	

This is how we applied the above steps in writing this program:-

1. Equate POLCAT to its Address

This equates POLCAT to \$A0000, the address that points to POLCAT's address:

POLCAT ECJU \$A000

2. Set Up Entry Conditions

POLCAT has no entry conditions.

3. Preserve the Registers' Contents

POLCAT's "Exit Conditions" state that POLCAT modifies all registers except B and X. Assume that you want to preserve the contents of Registers DP, CC, X, Y, and U. To do this, you can "push" these values into the "hardware stack":

(The hardware stack is an area of memory, pointed to by Register S, that the processor uses for subroutines. PSHS "preserves" the contents of certain registers by storing them in the hardware stack.)

4. Jump to POLCAT

This jumps to POLCAT using its indirect address:

5. Use Exit Conditions

For now, assume you want to look only at the status of Bit Z to see if a key has been pressed:

The above instruction branches back to WAIT (the JSR [POLCAT] instruction) unless you press a key. (Pressing a key causes POLCAT to clear Bit Z.)

6. Restore the Register's Contents

This "pulls" (inserts) the contents of the hardware stack back into the registers:

Now, the above registers are restored to the data they contained before executing the POLCAT routine.

Sample 2 Character Output with CHROUT

The CHROUT routine prints a character on either the screen or printer. On entry, it checks two places:

- Register A to determine which character to print
- Address \$6F to determine whether to print it on the screen or the printer

This program uses CHROUT to print 'This is a Message" on the screen. It then uses POLCAT to wait for you to press a key before returning to BASIC.

```
ORG $1200
*****Equates for Routines *****
POLCAT
               EQU
                       $A000
               EQU
                       $A002
CHROUT
DEVNUM
               EQU
                       $BF
***********Variable ********
SCREEN
        EQU
***DOS Programming Convention ***
        JMP
               START
BEGIN
        FDB
               DONE-BEGIN
****** Print the Message ******
START
        LDB
               #SCREEN
               DEVNUM
        STB
        LDX
               #MSG
PRINT
        LDA
               , \times +
        JSR
               [CHROUT]
               #$00
        CMPA
        BNE
                 PRINT
********Wait for a Key *******
INPUT
        PSHS
               DP,CC,X,Y,U
WAIT
        JSR
               [POLCAT]
        BEO
               WAIT
        PULS
               DP,CC,X,Y,U
        CLR
               $71
        JMP
               [$FFFE]
******** Message ********
               'THIS IS A MESSAGE'
MSG
        FCC
        FCB
               $0D
****** Memory for Stack ******
DONE
        END
```

Most of the steps we used in writing this program are obvious. What may not be obvious is the way we set up CHROUT's entry conditions, Address \$6F and Register A.

These lines set Address \$6F to 00 (the screen):

```
DEVNUM EQU $6F
SCREEN EQU 00
START LOB #SCREEN
STB DEVNUM
```

Setting Register A involves two steps. First, point Register X to the message:

```
MSG FCC 'THIS IS A MESSAGE'
FCB $00
LDX #MSG
```

and then load Register A with each character in the message:

```
PRINT LDA ,X+

JSR [CHROUT]

CMPA #$00

BNE PRINT
```

Sample 3 POLCAT and CHROUT

This combines POLCAT with CHROUT. It prints on the screen whatever key you press. When you press ⊡ (hexadecimal OA), the program returns to BASIC:

```
ORG $1200
*****Equates for Routines *****
POLCAT EQU $A000
CHROUT EQU $A002
DEVNUM EQU $6F
```

```

Chapter 14/ Opening and Closing a Disk File DOS Routines — Part I

Because of the organization and timing of a disk, reading it and writing to it are complex. This is why you'll want to make use of DOS routines in your disk programs.

This chapter shows how to use DOS routines to open and close a disk file. The next chapter shows how to use them to read a disk and write to it. *Reference H* contains a complete list of all the DOS routines supported by Radio Shack.

Overview

All DOS routines, like ROM routines, have their own entry and exit conditions. However, most DOS routines have more involved entry conditions than do ROM routines. They require you to set up three areas in memory: two "buffers" and a "data control block."

Buffers

Buffers are areas in memory that DOS uses for storing data to be input or output to disk. DOS requires that you reserve two buffers:

- A logical buffer This can be any length. Your program uses this to store data for DOS to input or output to disk.
- A physical buffer This must be 256 bytes. DOS uses this to hold data temporarily so that it can input and output the data to a disk sector in 256-byte blocks.

For example, suppose you want to output 100 10-byte records to disk. You can send each record, one at a time, to the area you reserved as the logical buffer.

DOS then transfers the records from the logical buffer to the area you reserved as the physical buffer. As soon as there are 256 bytes in the physical buffer, DOS sends them out to a disk sector.

You need not be concerned that DOS' "physical" records are a different size from your program's "logical" records. DOS handles the "spanning" of logical records into physical records internally. Except for reserving memory for a physical buffer, you do not need to be concerned with physical records.

Data Control Block

A data control block is a 49-byte "block" of memory that DOS uses to control a disk file. You need to reserve this block of memory for each disk file you are using. If you have three disk files open at the same time, you need to reserve three 49-byte data control blocks.

Reference G shows how DOS uses each of the 49 bytes, numbered 0-48, in the data control block. As you can see, DOS divides the data control block into 21 data-control segments.

Before opening a file, you must load the proper data into four of the segments of the data control block (DCB):

DCB Segment	DCB Address	You must load with
Filename (DCBFNM)	Bytes 0-7	The eight- character name of your file.
Extension Bytes (DCB EXT)	8-10	The three character extension of your filename.
Drive Number (DCBDRV)	Byte 33	The drive containing the disk file.

Physical Byte 36-37
Buffer Address
(DCBBUF)

The first address of the physical buffer you have reserved.

For example, if you want to open a file in Drive 1, you need to load "1" into the DCBDRV location, which is the 33rd byte of the data control block.

You need not be concerned with most of the remaining segments of the data control block, unless you want to use them as data in your program. They are handled internally by DOS. The exceptions to this are:

- Logical Buffer Address, Record Size, Variable Record Terminator, and Logical Record Number - You need to use these when you read and write to the file. They are discussed in the next chapter.
- File Type and ASCII Flag- If you want your file to be compatible with BASIC and other Radio Shack programs, you need to set these when you create the fire. See the "Technical Information" chapter of your *Disk System Owners Manual and Programming Guide*.

Steps for Using DOS Routines

The steps for using DOS routines are:

- 1. Equate the routine's address (for ease in reading the program).
- 2. Reserve memory for a physical buffer, logical buffer, and the DCB.
- 3. Clear the DCB and the physical buffer. You need to make sure they do not have extraneous data.
- 4. Set up all other entry conditions. Besides setting up registers, you need to load certain segments of the DCB with data. Which segments you load depends on the DOS routine you are using.
- 5. Preserve the contents of the registers. DOS routines change the contents of many of the registers. To be safe, you should preserve all of them that you want to use later in your program. Be sure to preserve Registers U and DP. If DOS changes their contents, your program acts unpredictably.
- 6. Call the routine.
- 7. Restore the contents of the registers.

8. Use all exit conditions. Most DOS routines return an error code in Register A if the routine did not work properly. If there were no errors, Register A contains a zero.

Sample Session Opening and Closing a Disk File

The DOS routines for opening and closing a file are OPEN and CLOSE. Both routines check Register U for the address of DCB. They expect to find the four segments described above in this block.

OPEN also expects you to set a file mode in Register A. It creates or opens an existing file depending on the mode you set.

Both routines return a status code in Register A. *Reference I* tells the meaning of the status codes.

Figure 8 at the end of this chapter is a sample program which creates, opens, and closes a disk file named WORKFILE/TXT. After running this program, you can look at your directory to see that the program has created this file. This shows how we applied the above steps in this program.

1. Equate OPEN and CLOSE

This equates OPEN and CLOSE to \$600 and \$602, their indirect addresses:

OPEN EQU \$600 CLOSE EQU \$602

2. Reserve Memory for Buffers and DCB

The OPEN and CLOSE routines use only the physical buffer, not the logical buffer. This stores 256 bytes for the physical buffer and uses PBUF to label those bytes:

PBUF RMB 256

This reserves memory for a 49-byte DCB and stores the filename, WORKFILE, and the extension, TXT, in the first 11 bytes:

DCB EQU *
FCC 'WORKFILE'
FCC 'TXT I'
RMB 38

3. Clear DCB

This clears all but the first 11 bytes of DCB:

RCLEAR	LDX	#DCB+11
CLEAR1	CLR	, X+
	CMPX	#DCB+48
	BNE	CLEAR1
	LDX	#PBUF

and this clears the physical buffer:

CLEAR2	CLR	,×+
	CMPX	#PBUF+255
	BNE	CLEAR2
	RTS	

4. Set Up Entry Conditions

On entry, OPEN and CLOSE require you to: (1) Set Register U to a DCB containing a filename, extension, drive number, and physical buffer address, and (2) Set Register A to a file mode.

Setting Register U

This sets Register U to the address of the first byte of the DCB:

ı	DL	I	#	m	~	D	
L	υı	J	₩	D	Ŀ	Б	

The following lines set the drive number segment to 0. They do this by storing DRVNUM (0) into DCBDRV (33) + the contents of Register U (DCB). This inserts 0 into the 33rd byte of DCB:

DCBDRV	EQU	33
DRVNUM	FCB	00
	LDA	DRVNUM
	STA	DCBDBV.II

The following lines set the physical buffer address to PBUF. They do this by storing the address of PBUF into the memory address pointed to by Register U plus DCBBUF. This stores PBUF in the 36th byte of DCB:

DCBBUF	EQU	36
	LDX	#PBUF
	STX	DCBBUF,U

(The filename and extension were set in Step 2.)

Setting Register A

This table shows how you should set each bit in Register

A to select one or more file modes:

BIT	DECIMAL NUMBER
	(IF SET)
Bit 0	1
Bit 1	2
Bit 2	4
Bit 3	8
Bit 4	16
when closed)	
Bit 5	32
FAT* only when	closed)
Bit 6	64
	Bit 0 Bit 1 Bit 2 Bit 3 Bit 4 when closed) Bit 5 FAT* only when

^{*} The disk directory's FAT (file allocation table) is described in the "Techncial Information" chapter of the Disk System Manual.

The sample program loads Register A with decimal 1+2+4+8+32:

This tells DOS to set the file mode to read (decimal 1), write (decimal 2), create (decimal 4), extend (decimal 8), and rewrite the FAT only when the file is closed (decimal 32).

5. Preserve Registers

This preserves the contents of Registers U and DP:

ROPEN PSHS U.DP

6. Jump to the DOS Routine

These lines jump to OPEN and CLOSE:

JSR	0	P	Ε	M]	
JSR	C	L	0	S	Ε]

7. Restore Registers

This restores the contents of Registers U and DP:

PULS U.DP

8. Use Exit Conditions

The sample program branches to an error handling subroutine after each DOS routine. The subroutine tests Register A to see if it contains a non-zero value. If so, it

prints the status coopress a key:			CLEAR2	CLR CMPX BNE	,X+ #PBUF+255 CLEAR2

Chapter 15/ Reading and Writing a Disk File DOS Routines — Part 2

DOS has a WRITE routine for writing to a file and a READ routine for reading it back into memory. The way you use these routines depends on which method you are using to access the file:

- Sequential Access
- Direct Access

This chapter describes how to use these two methods in their simplest forms. You can use any variation of them that you want. When reading data from just one file, you need only specify the logical buffer address, not the terminator character. DOS reads the terminator character from the disk's directory into DCBTRM.

Figure 9 at the end of this chapter is a program that writes to a file using \$OD (the ENTER character) as a terminator character. Figure 10 reads the same file back into memory.

Sequential vs. Direct Access

Sequential Access

(For Files with Variable-Length Records)

Sequential access lets you read and write to files with variable-length records. Using this method, you insert a terminator character at the end of each record. This character tells DOS where each record ends.

Before writing data to the file, you must load DCB with the following:

DCB Segment	DCB Address	You must load with
Logical Buffer Address (DCBLRB)	Bytes 39-40	The first address of the logical buffer you have reserved
Terminator Character (DCBTRM)	Byte 19	The character you select to end each record

Direct Access

(For Files with Fixed-Length Records)

Direct access works only with files containing fixed length records. With this method, DOS uses the record size and record number to access the record.

Before reading data from the file or writing data to it, you must set this DCB segment:

DCB Segment	DCB Address	You must load with
Logical Buffer Address (DCBLRB)	Bytes 39-40	The address of the first byte of the logical buffer you have reserved
Unless you are using directory, you must a	•	already in the file's
Logical Record	Bytes 17-18	The size of each record
Size (DCBRSZ)		

If you want to write a record which is not sequentially the next one, you must also set:

Logical Bytes 46-47 The number of Record Number (DCBLRN) the record you want to access

Setting the Read/Write Option

DOS requires that you set Register A with a "read/write option" before entering the READ or WRITE routines. The read/write option lets you specify:

- Whether you want direct or sequential access
- Whether you want DOS to point to the next record after reading or writing the record

To set the read/write option, load the first two bits of Register A with one of these four values:

Read/Write Option	Bits	Decimal Number
Direct Access Point to next record	00	0
Sequential Access Point to next record	01	1
Direct Access Do not point to next	10 record	2
Sequential Access Do not point to next	11 record	3
For example:		
LDA JSR	#2 [READ]	

tells DOS to write the record sequentially (up to the terminator character). When finished, DOS points to the next sequential record.

SECTION V/
REFERENCE

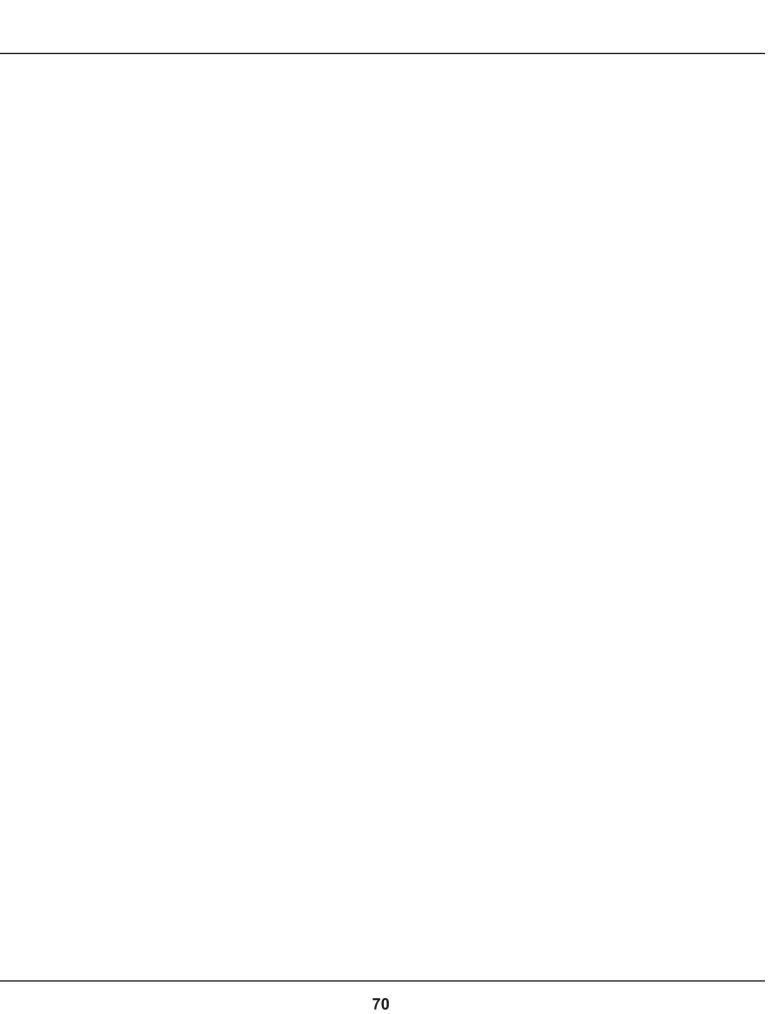

SECTION V/

REFERENCE

This section summarizes all the features of the Disk EDTASM.

Reference A/ Editor Commands

Definition of Terms

line

A line number in the program. Any lines between 0-63999 may be used. These symbols may be used:

- # First line in the program
- * Last line in the program
- . Current line in the program

current line

The last line inserted, edited, or printed.

startline

The line where an operation will begin. In most commands startline is optional. If startline is omitted, the current line is used.

An asterisk(*) denotes a comment line when used as the first character in the line.

range

The line or lines to use in an operation. If the range includes more than one line, they must be specified with one of these symbols:

- : to separate the startline from the ending line
- , to separate the startline from the number of lines

Increment

The increment to use between lines. In most commands, increment is optional. If the increment is omitted, the last specified increment is used. On startup, increment is set to 10.

filespec

A DOS disk file specification in the format:

filename/ext:drive

COMMANDS	PAGES
	DISCUSSED

Cstartline, range, increment

Copies range to a new location beginning with startline using the specified increments. startline, range, and *increment* must be included.

C500,100:150,10

Drange

Deletes range. If *range* is omitted, *current line* is deleted.

D100 D100:150 0

Eline

Enters a *line* tor editing. If line is omitted, *current line* is used.

E100 E

These are the editing subcommands:

A Cancels all changes and restarts the edit.

nCstring Changes *n* characters to *string*. If *n* is omitted, changes

the character at the current cursor position.

nD Deletes n characters. If n is omitted, deletes character at

current cursor position.

E Ends line editing and enters all changes without displaying

the rest of the line.

H Deletes rest of line and allows insert.

I string Inserts *string* starting at the current cursor position.

While in the mode,

deletes a character, and

SHIFT

⚠ ESC ends the mode.

K Deletes all characters from the current cursor position to

the end of the line.

L Lists current line and continues edit.

nScharacter Searches for *n*th occurrence of character. If *n* is omitted,

searches for the first occurrence.

X Extends line.

ENTER SPACEBAR SPACEBAR Ends line editing, enters all changes and displays the

rest of the line. SPACEBAR

SPACEBARI SPACEBARI Escapes from subcommand.

n[SPACEBAR] SPACEBAR] Moves cursor *n* positions to the right. If *n* is omitted,

moves one position. SPACEBAR

 $n \in SPACEBAR SPACEBAR SPACEBAR Moves cursor n positions to the left. If n is omitted,$

moves the cursor one position. SPACEBAR

SPACEBAR

FstrIng

Finds the string of characters. Search begins with the current line and ends each time string is found. If string is omitted, the last string defined is used.

FABC F

Hrange

Prints range on the printer. If range is omitted, the current line is printed.

H100 H100:200 H

Istartline,increment

Inserts lines up to 127 characters long beginning at startline, using the specified increment. startline and increment are optional.

I150,5 1200 I,10

Κ

Returns to DOS.

LCA filename

Loads *filename* from tape into the edit buffer. A is optional. If included, *filename* is appended to the edit buffer. If *filename* is omitted, the next tape file is loaded.

LC SAMPLE/EXT

LCA SAMPLE/EXT

LOA filespec

Loads the specified file from disk into the edit buffer. A is optional. If included, *filespec* is appended to the current contents of the edit buffer. If extension is omitted, /ASM is used.

LO SAMPLE/EXT LOA SAMPLE/EXT

Mstartline, range, Increment

Move command, works like copy except the original lines are deleted.

Nstartline, Increment

Renumbers beginning at startline, using the specified increment. startline and increment are optional.

N100,50

M100

Ν

0

Shows the hexadecimal values of (1) the first available memory address, (2) the last available address, and (3) USRORG, the address where the assembler originates an /IM assembly with the /MO switch. Then, prompts you to change USRORG.

0

Prange

Displays range on the screen.

P100:200 P100!5 P# P+ P (Prints 15 lines to the screen)

Q

Returns to BASIC.

R startline, increment

Allows you to replace startline and then insert lines using increment. startline and increment are optional.

R100,10

R100

R

S

Shows the current printer parameters and lets you change them.

Trange

Prints range to the printer, without line numbers.

T100:500

Vfilename

Verifies *filename* (a tape file) to ensure that it is free of checksum errors. Works like BASIC's SKIPF command. If *filename* is omitted, this command verifies the next file found.

WC filename

Writes filename to tape. If *filename* is omitted, NONAME is used.

A / EDITOR COMMANDS

WD filespec

Writes *filespec* to disk. If the extension is omitted, ASM is used.

WD SAMPLE/EXT

Ζ

Jumps to ZBUG (EDTASM system only).

1

Scrolls up in memory.

 \downarrow

Scrolls down in memory.

SHIFT CLEAR

Is used to create a backslash (\).

Reference B/ Assembler Commands and Switches

COMMANDS PAGES
DISCUSSED

AC filename switch ...

Assembles the source program into machine code. If you specify the /IM switch, the assembly is in memory. If you specify *filename*, the assembly is saved on tape as *filename*. If you omit both *filename* and *switch*, the assembly is saved on tape as NONAME.

AD fllespec switch ...

Assembles the source program into machine code. Either the /IM switch or *filespec* is required: With /IM, the assembly is in memory; with *filespec*, the assembly is on disk. The D is optional.

There must be a space between filespec and switch.

The switches are:

/AO Absolute origin.(Applies only If /IM is set.)

/IM In-memory assembly.

/LP Assembly listing on the printer.

/MO Manual origin. (Applies only if /IM is set.)

/NL No listing printed.

/NO No object code generated.
/NS No symbol table generated.

/SR Single record. /SS Short screen.

/WE Wait on assembly errors.

/WS With symbofs.

Examples:

AD SAMPLE
AD/IM/AO
AD SAMPLE /WE/SR
A SAMPLE/TST /WE
AC SAMPLE
AC

Reference C/ ZBUG Commands

Definition of Terms

expression

One or more numbers, symbols, or ASCII characters. If more than one is used, you may separate them with these operators:

Multiplication	*	Addition	+
Division	.DIV	Subtraction	_
Modulus	.MOD	Equals	.EQU
Shift	<	Not Equal	.NEG
Local And	.AND	Positive	+
Exclusive Or	.XOR	Negative	_
Logical Or	.OR	Complement	.NOT

address

A location in memory. This may be specified as an expression using numbers or symbols.

filename

A BASIC cassette file specification.

fllespec

A DOS file specification. (The same as a BASIC specification.)

COMMANDS	PAGES
	DISCUSSED

C

Continues execution of the program after interruption at a breakpoint.

D

Displays all breakpoints that have been set.

F

Exits ZBUG and enters the editor. (This applies to the EDTASM ZBUG only, not to Stand-Alone ZBUG.)

Gaddress

Executes the program beginning at address.

Κ

Returns to DOS. (Applies to Stand-Alone ZBUG only.)

LC filename address

Loads filename from tape. The optional address offsets the file's loading address. If filename is omitted, the next file is loaded.

LD filespec address

Loads *filespec* from disk. The optional address offsets the file's loading *address*.

LDS filespec address1 address2

Loads filespec from disk with its appended symbol table. The optional address1 offsets the file's loading address. The optional address2 offsets the symbol table's loading address. Note that address2 does not offset the values of the symbols. The D is optional.

PC filename start address end address execution address

Saves memory from start address to end address to tape. You must also specify an execution address, the first address to be executed when the file is loaded. Filename is optional; if omitted, NONAME is used.

PD filespec start address end address execution address

Saves memory to disk from start address to end address. You must also specify an execution address, the first address to be executed when the file is loaded. (The D is optional.)

PDS filespec start address end address execution address

Saves memory to disk from start address to end address, with the current appended symbol table. You must also specify an execution address, the first address to be executed when the file is loaded. (The D is optional.)

Q

Returns to BASIC. (Applies to Stand-Alone ZBUG only.)

Displays the contents of all the registers.

Taddress1 address2

Displays the memory locations from address1 to address2, inclusive.

THaddress1 address2

Prints the memory locations from address1 to address2, inclusive.

Usource address destination address count

Transfers the contents of memory beginning at source address and continuing for count bytes to another location in memory beginning with destination address.

Vfilename

Verifies date on the specified file or, if no *filename* is specified, the next file on tape.

Sets a breakpoint at address. If address is omitted, the current location is used. Each breakpoint is assigned a number from Oto 7. The first breakpoint set is assigned as Breakpoint 0. A maximum of eight breakpoints may be set at one time.

Yn

Deletes the breakpoint referenced by the *n* number. If *n* is omitted, all breakpoints are deleted.

Examination Mode Commands

A ASCII Mode
B Byte Mode
M Mnemonic Mode
W Word Mode

(The default is M)

Display Mode Commands

H Half SymbolicN NumericS Symbolic

(The default is S)

Numbering System Mode Commands

Obase Output Ibase Input

(Base can be 8, 10, or 16. The default is 16)

Special Symbols

address/ register/

Opens address of register and displays its contents.

If *address* or *register* is omitted, the last address opened will be reopened. After the contents have been displayed, you may type:

new value To change the contents.

To close and enter any change.To close and delete any change.

d To open next *address* and enter any change.

u To open preceding *address*.

address ■ To branch to the address pointed to by the instruction

beginning at address. If address is omitted, the current

address is used.

; To force numeric display mode. = To force numeric and byte modes.

: To force flags.*

" To force ASCII mode.

address,

Executes *address*, if address is omitted, the next instruction is executed.

expression=

Calculates expression and displays the results.

* The colon does not actually have anything to do with the CC (status flag) register. It simply interprets the contents of the given address AS IF it contained flag bits.

Reference D/ EDTASM Error Messages

These are error messages you can get while in EDTASM or EDTASMOV:

BAD BREAKPOINT (ZBUG)

You are attempting to set a breakpoint (1) greater than 7, (2) in ROM, (3) at a SWI command, (4) at an address where one is already set.

BAD COMMAND (Editor)

An illegal command letter was used on the command line.

BAD COMMAND (ZBUG)

You are not using a ZBUG command.

BAD FILE DESCRIPTOR (Disk,ZBug)

The filespec is not in the proper DOS format. See "About This Manual" at the beginning of this manual for the proper file specification format.

BAD LABEL (Assembler)

The symbol you are using is (1) not a legal symbol, (2) not terminated with either a space, a tab, or a carriage return, (3) has been used with ORG or END, which do not allow labels, or (4) longer than six characters.

BAD MEMORY (Assembler)

You are attempting to do an in-memory assembly that would (1) overwrite system memory (an address lower than \$1200) (2) overwrite the edit buffer of the symbol table, (3) go into the protected area set by USROG, or (4) go over the top of RAM.

If using the /AO switch, check to see that you've included an ORG instruction. When using /MO, check the addresses you set for BEGTEMP and USRORG. This could also be caused by the data not being stored correctly because of some code generated by an inmemory assembly. See *Chapter 7* for more information.

BAD MEMORY (ZBUG)

The data did not store correctly on a memory modification. This error will occur if you try to modify ROM addresses or try to store anything beyond MAXMEM.

BAD OPCODE (Assembler)

The op code is either not valid or is not terminated with a. space, tab, or carriage return.

BAD OPERAND (Assembler)

There is some syntax error in the operand field. See Section III for the syntax of assembly language instructions.

BAD PARAMETERS (Editor, ZBug)

Usually this means your command line has a syntax error.

BAD PARAMETERS (ZBUG)

You have specified a filename that has more than eight characters.

BAD RADIX (ZBUG)

You have specified a numbering system other than 10, 8 or 16.

BUFFER EMPTY (Editor)

The specified command requires that there be some text in the Edit Buffer, and there isn't any.

BUFFER FULL (Editor)

There is not enough room in the edit buffer for another line of text.

BYTE OVERFLOW (Assembler)

There is a field overflow in an 8-bit data quantity in an immediate operand, an offset, a short branch, or an FCB pseudo op.

DIRECTORY FULL (Disk)

The directory does not have enough room for another entry. Use another diskette or delete a file (using the BASIC KILL command).

DISK FULL (Disk)

The diskette does not have enough room for another file. Use another diskette or delete a file (using the BASIC KILL command).

DISK WRITE PROTECTED (Disk)

You are attempting to write to a diskette that has the writeprotect notch covered. Remove the write-protect label or use another diskette.

DOS ERROR (Disk)

This indicates an internal DOS error. It usually means either the DOS or the Editor/Assembler has been modified by the user program with harmful results.

DP ERROR (Assembler)

Direct Page error. The high order byte of an operand where direct addressing has been forced (,) does not match the value set by the most recent SETDP pseudo op.

DRIVE NOT READY (Disk)

The drive is not connected, powered up, working properly, or loaded properly.

END OF FILE (Disk)

Your program is attempting to access a record past the end of the file.

ENDC WITHOUT COND (Assembler)

The pseudo op ENDC was found without a matching COND having previously been encountered.

ENDM WITHOUT MACRO (Assembler)

The pseudo op ENDM was found without a matching MACRO having previously been encountered.

EXPRESSION ERROR (Assembler and ZBUG)

Either the syntax for the expression is incorrect (check *Chapter 9*) or the expression is dividing by zero.

FILE NOT FOUND (Disk)

The file is not on the disk's directory.

FM ERROR (Editor, ZBUG and Disk)

File Mode Error. The file you are attempting to load is not a TEXT file (if in the Editor) or a CODE file (if in ZBUG).

ILLEGAL NESTING (Assembler)

Illegal nesting conditions include the following:

- 1. Nested macro definitions.
- 2. Nested macro expansions.
- 3. Nested INCLUDE pseudo ops.
- 4. INCLUDE nested within a macro definition.

I/O ERROR (Editor, ZBUG and Disk)

Input/Output error. A checksum error was encountered

while loading a file from a cassette tape. The tape may be bad, or the volume setting may be wrong. Try a higher volume.

MACRO FORWARD REFERENCE

(Assembler)

A reference to the macro, which is defined on the current line, occurs previous to the macro definition.

MACRO TABLE FULL (Assembler)

The macro table is full, any additional entries will overwrite the symbol table. This happens when all memory allocated for the edit buffer, macro table, and symbol table has been used. Adjust USRORG using the Origin (0) command. (See the *Chapter 7*.)

MISSING END (Assembler)

Every assembly language program must have END as its last command.

MISSING INFORMATION (Assembler)

- (1) There is a missing delimiter in an FCC pseudo op or
- (2) there is no label on a SET or EQU pseudo op.

MISSING OPERAND (Assembler, ZBug)

The command requires one or more operands.

MULTIPLY DEFINED SYMBOL (Assembler)

Your program has defined the same symbol with different values. If the error occurs in a macro expansion, use the /.1 notation to name the symbols. See *Chapter 12*.

NO ROOM BETWEEN LINES (Editor)

There is not enough room between lines to use the increment specified. Specify a smaller increment or renumber (N) the text using a larger increment. Remember that the last increment you used is kept until you specify a new one.

NO SUCH LINES (Editor)

The specified line or lines do not exist.

REGISTER ERROR (Assembler)

(1) No registers have been specified with a PSH/PUL instruction, (2) a register has been specified more than once in a PSH/PUL instruction, or (3) there is a register mismatch with an EXG/TFR instruction.

SEARCH FAILS (Editor)

The string specified in the Find (F) command could not be found in the edit buffer beginning with the line specified. If no line is specified the current line is used.

SYMBOL TABLE OVERFLOW (Assembler)

The symbol table is extending past USRORG into the protected area of user memory. Adjust USRORG using the 0 command. See Chapter 7.

SYNTAX ERROR (Assembler)

There is a syntax error in a macro dummy argument.

UNDEFINED SYMBOL (Assembler, ZBug)

Your program has not defined the symbol being used.

Reference E/ Assembler Psuedo Ops

Definition of Terms

symbol

Any string from one to six characters long, typed in the symbol field.

expression

Any expression typed in the operand field. See Reference C, "ZBUG commands," for a definition of valid expressions.

C	COMMANDS	PAGES DISCUSSED
		2.000022

COND expression

Assembles the instructions between COND and ENDC only if expression is true (a non-zero value).

COND SYMBOL
SYMBOL FCB 10
VALUE FCB 5

COND SYMBOL-VALUE

Valid operators for a conditional expression are +, —, /, *. If the expression equals zero, it is false; if non-zero, it is true.

END expression

Ends the assembly. The optional expression specifies the start address of the program.

ENDC

Ends a conditional assembly.

ENDM

Ends a macro definition.

symbol EQU expression

Equates symbol to an expression.

SYMBOL EQU \$5000

symbol FCB expression, ...

Stores a 1-byte *expression* beginning at the current address.

DATA2 FCB

\$33+COUNT

symbol FCC delimiter string delimiter

Stores *string* in memory beginning with the current address. The delimiter can be any character.

TABLE

FCC

/THIS IS A STRING/

symbol FDB expression

Stores a 2-byte expression in memory begining at the current address.

DATA

FDB

\$3322

INCLUDE source fllespec

Includes source *filespec* in the current position of the source program.

INCLUDE

SAMPLE/ASM

symbol MACRO

Defines the instructions between MACRO and ENDM as a macro named symbol.

DIVIDE MACRO

OPT switch, ...

Uses *switch* to control the listing of macros when assembling the program. The switches are:

MC List macro calls (default)
NOMC Do not list macro calls

MD List macro definitions (default)
NOMD Do not list macro definitions
MEX List macro expansionns

NOMEX Do not list macro expansions (default)

L Turn on the listing (default)

NOL Turn off the listing

ORG expression

Originates the program at expression address.

ORG

\$3F00

PAGE

Ejects the assembly listing to the next page.

RMB expression

Reserves expression bytes of memory for data.

DATA RMB \$08

symbol SET expression

Sets or resets symbol to expression.

SYMBOL SET \$3500

SETDP *expression*

Sets the direct page to expression.

SETDP \$20

TITLE string

Prints *string* as the title of each page of the assembly listing. *String* can be up to 32 characters.

TITLE Progam 1

Reference F/ Rom Routines

This reference lists the indirect addresses where the Color Computer's ROM routines are stored. It also shows the entry and exit conditions for each routine.

The name of the routine is for documentation only. To jump to the routine, you must use its indirect address (the address contained in the brackets).

COMMANDS PAGES
DISCUSSED

BLKIN = [\$A006]

Reads a block from a cassette.

Entry Conditions:

Cassette must be on and in bit sync (see CSROON).

CBUFAD contains the buffer address.

Exit Conditions:

BLKTYP, located at \$7C, contains the block type:

0 =file header

1 =data

FF= end of file

BLKLEN, located at \$70, contains the number of data bytes in the block (0-255):

Bit Z in the Register CC, Register A, and CSRERR, located at Address \$81, contains the error:

Z = 1, A = CSRERR = 0 (if no errors)

Z = 0, A = CSRERR = 1 (if a checksum error occurs)

Z = 0, A= CSRERR = 2 (if a memory error occurs)

BLKOUT = [\$A008]

Writes a block to cassette.

Entry Conditions:

If this is the first block write after turning the motor on, the tape should be up to speed and a \$55s should be written first.

CBUFAD, located at \$7E, contains the buffer address.

BLKTYP, located at \$7C, contains the block type.

BLKLEN, located at \$70, contains the number of bytes.

Exit Conditions:

Interrupts are masked.

X = CBUFAD + BLKLEN.

All registers are modified.

CHROUT = [A002]

Outputs a character to a device.

Entry Conditions:

Register A = character to be output

Address 6F (DEVNUM) = the device (-2 = printer; 0 = screen)

Exit Conditions:

Register CC is changed; all others are preserved.

CSRDON = [\$A004]

Starts the cassette and gets into bit sync for reading.

Entry Conditions:

None

Exit Conditions:

FIRQ and IRO are masked.

Registers U and Y are preserved. All others are modified.

JOYIN = [\$A00A]

Samples the four joystick pots and stores their values in POTVAL through POTVAL + 3.

Left Joystick:

Up/Down 15A Right/Left 15B

Right Joystick:

Up/Down 15C Right/Left 15D

For Up/Down, the minimum value equals Up. For Right/Left, the minimum value equals Left.

POLCAT = [A000]

Polls the keyboard for a character.

Entry Conditions:

None

Exit Conditions:

If no key is seen — Flag Z = 1, Register A = O

If a key is seen — Flag Z = 0, Register A = key code

Registers Band X are preserved.

All other registers are modified.

Reference G/ DOS Disk Data Control Block (DCB)

DOS uses a 49-byte DCB to access a disk file. This reference shows the contents of each of the bytes (Bytes 0-48) in the DCB.

Bytes 0-31

The first 32 bytes of the DCB correspond to the disk file's 32-byte directory entry. When creating a file, DOS writes the DCB's first 32 bytes to the directory.

When opening an existing file, DOS searches each directory entry for the filename and extension you have set in the DCB. If it finds a match, it overwrites the first 32 bytes of the DCB with the 32-byte directory entry.

When you close the file, DOS overwrites the directory entry with the first 32 bytes of the DCB.

Filename (DCBFNM)

Bytes 0-7

Contains the name of the file you want to access. You must set this value.

Extension (DCBFNM)

Bytes 8-10

Contains the extension of the file you want to access. You must set this value.

File Type (DCBFTY)

Byte 11

Contains the type of file you want to access. DOS ignores this, but BASIC uses it. You need to set this value when creating the file if you want the file compatible with BASIC.

ASCII Flag (DCBASC)

Byte 12

Contains a flag if the file is in ASCII format. DOS ignores this, but BASIC uses it. You need to set this value when creating the file if you want the file compatible with BASIC.

First Cluster (DCBFCL)

Byte 13

Contains the number of the first cluster in the file. (When you first create a file, this contains \$FF.) DOS sets this value .. Do not change it.

First Sector Bytes (DCBNLS)

Bytes 14-15

Contains the number of bytes used in the first sector of the file. DOS ignores this. However, tobe compatible with BASIC files, you should set this value before closing an output file.

File Mode (DCBCFS)

Byte 16

Contains the mode you specified with Register A in the OPEN, WRITE, or READ routine. DOS sets this value.

Record Size (DCBRSZ)

Bytes 17-18

Contains the size of each record. Use this with fixed-length records only. You set this value before reading from or writing to a direct access file.

Record Terminator (DCBTRM)

Byte 19

Contains the character that DOS uses to terminate each record. You supply this value when reading from or writing to a sequential access file.

Undefined (DCBUSR)

Bytes 20-31

Contains nothing at present. In future releases, DOS may use part of this.

Bytes 32-48

Bytes 32-48 are primarily set by DOS. However, you may use the contents of these bytes as data in your program.

The exceptions to this are the bytes for the drive number, physical buffer address, and logical buffer address. You must set the contents of these bytes before opening a file.

Operation Code (DCBOPC)

Byte 32

Contains the last physical 1/0 operation performed on the file. See your Disk System Manual for details. DOS sets this value.

Drive Number (DCBDRV)

Byte 33

Contains the drive number (0-3 or \$FF). \$FF tells DOS to use the first available drive and then insert the drive number in this segment. You must set this value before opening a file.

Track Number (DCBTRK)

Byte 34

Contains the number of the last track DOS accessed while doing 1/0 for this file. DOS sets this value.

Sector Number (DCBSEC)

Byte 35

Contains the number of the last sector DOS accessed while doing 1/0 for this file. DOS sets this value.

Physical Buffer Address (DCBBUF)

Bytes 36-37

Contains the start address of a 256-byte physical buffer. The physical buffer is for storing data before or after disk 1/0. You must set this value before opening a file.

Error Code (DCBOK)

Byte 38

Contains the same value that the DOS routine returns in Register A: a zero if the last DOS routine was successful; the error number if there was an error. DOS sets this value.

Logical Buffer Address (DCBLRN)

Bytes 39-40

Contains the start address of a logical buffer. The logical buffer is for storing a logical record before or after it goes through the physical buffer. You must set this value before opening a file, unless you have specified the "share" file mode. (See OPEN.)

Physical Record Number (DCBPRN).

Bytes 41-42

Contains the number of the physical record currently in the physical buffer. DOS uses this to determine whether another physical read or write is required. This contains \$FFFF when the file is opened. It also contains \$FFFF after every read or write when the buffer is "shared." DOS sets this value.

Relative Byte Address (DCBRBA) Bytes 43-45

Contains an address which points to the record you want to read or write (zero when the file is first opened). With sequential access, this address always points to the next record. With direct access, this address is the product of DCBRSZ times DCBPRN. DOS sets and updates this value.

Logical Record Number (DCBLRN). Bytes 46-47

Contains the number of the next record to be accessed (zero when the file is first opened). Unless you set this value, DOS increments it after accessing each record.

Modified Data Tag (DCBMDT) Byte 48

Contains a tag ("1") if the contents of the physical buffer need to be written to disk. DOS sets this tag each time it writes to the logical buffer. The contents of the physical buffer are written to disk only when DOS must access a different sector (because the 256-byte buffer is full) or close the file. If the physical buffer is "shared," the physical buffer is written to disk after each logical write. DOS sets and updates this value.

Reference H/DOS Routines

This reference lists all the DOS routines that Radio Shack will continue to provide in future releases. Please note that Radio Shack will support only the OPEN, CLOSE, READ, and WRITE routines. The other routines listed in this reference will be provided, but not necessarily supported.

Definition of Terms

root program

The portion of the program that is not an overlay. If you are not using overlays, this is the entire program.

overlay

A portion of the program that DOS loads into memory only when called. This can be your own overlay (called with DOUSR, GOUSR, or LOUSR) or a DOS overlay (called with DO, GO, or LOAD).

DOS programming convention

A convention, which any program using DOS routines must follow:

- The execution address must be the first instruction in the program.
- The first three bytes of the program must contain a JMP or LBR to any part of the root program. (JMP and LBR are both 3-byte instructions.) Example:

START JMP BEGIN

• The next two bytes must contain the length of the root program. If you are not using overlays, this is the entire program. Example:

FDB DONE-START

• If you are using overlays, this is the root program. Example:

FDB DONE-OVY1

DOS overlay conventions

A convention, which any of your own overlays must follow:

• The first two bytes must contain the size of the overlay. Example:

OVY1 FDB OVY2-OVY1

• The next three bytes must contain a JMP or LBRA to any part of the overlay. Example:

JSR PROV1

- The last instruction should be an RTS, GO, or GOUSR.
- You must assign the overlay a number that is sequential. For example, assign your first overlay the overlay number
 of 1:

OVY EQU 1

• The overlay must be written with relocatable (rather than absolute) addresses. When DOS loads the overlay, it sets Register X equal to the overlay's base address. Therefore, you can refer to all the local variables as an offset to Register X.

COMMANDS PAGES
DISCUSSED

CLOSE = [\$602]

Closes access to a disk file.

Entry Conditions:

Register U = the address of the DCB that was previously opened.

Program must follow DOS programming convention.

Exit Conditions

Register A = status code

Technical Function of CLOSE:

- Checks the drive specified by DCBDRV for a directory entry matching DCBFNM and DCBFEX. When the entry is found, checks to see if the file was previously open by seeing if DCBCFS contains a non-zero value.
- Checks DCBMDT for a modification tag. If found, writes the contents of the physical buffer to the disk.
- Sets DCBCFS to zero.
- Rewrites the directory entry with the first 32 bytes of the DCB. Any changes in the first 32 bytes of the DCB after OPEN and before CLOSE are recorded in the directory.
- Rewrites the diskette's FAT.

DO= [\$60A]

Calls a DOS overlay.

Entry Conditions:

Register A = DOS overlay number

Exit Conditions:

Register A = status code

DOUSR = [\$0610]

Calls one of your own overlays.

Entry Conditions:

Register A = overlay number (the number you have assigned to the overlay)

Exit Conditions:

Register A = status code

GO= [\$60C]

Calls one DOS overlay from another DOS overlay.

Entry Conditions:

Register A = DOS overlay number

Exit Conditions:

Register A = status code

GOUSR = [\$612]

Calls one overlay from another overlay. For example, OVY1 calls OVY2.

Entry Conditions:

Register A = overlay number (the number you have assigned to the overlay)

Exit Conditions:

Register A = "0" if no error; error code if error

LOAD = [\$60E]

Loads a DOS overlay but does not execute it.

Entry Conditions:

Register A = DOS overlay number

Exit Conditions:

Register A = "0" if no error; error code if error

LODUSR = [\$614]

Loads one of your overlays but does not execute it.

Entry Conditions:

Register A = overlay number (the number you have assigned to the overlay)

Exit Conditions:

Register A = "0" if no error; error code if error

OPEN = [\$600]

Opens access to a disk file using the specified file mode.

Entry Conditions:

Register A = file mode

The file modes are:

Bit 0 set — allows reads

Bit 1 set — allows writes

Bit 2 set — allows file creation

Bit 3 set — allows extension past end of file

Bit 4 set — deletes the file when closed (work file)

Bit 5 set — rewrites the directory's file allocation table (FAT) only when the file is closed. (Otherwise, rewrites FAT after each READ; see the *Disk System*

Manual for information on the FAT.)

Bit 6 set — shares the physical and logical buffer

Bit 7 set — undefined

Register U = the address where the DCB is stored.

The DCB must contain values for DCBFNM, DCBFEX, DCBDRV, and DCBBUF

Program must follow DOS programming conventions.

Exit Conditions:

Register A = 0 if no error; error code if error

Technical Function of OPEN:

- Checks the drive specified by DCBDRV for a directory entry matching DCBFNM and DCBFEX.
- · If a match is found:
 - Uses the directory entry to overwrite the first 32 bytes of the DCB
 - Checks DCBCFS. It indicates a write, create, or extend, the file is opened and Status Code Lis returned.
 - Inserts the file mode (contained in Register A) in DCBCFS.
 - Overwrites the directory entry with the first 32 bytes of the DCB.
 - If a match is not found and the file mode is "create," creates a directory entry using the first 32 bytes of the DCB

- · Sets DCBPRN to \$FFFF
- · Clears DCBLRN, DCBMDT, and DCBRBA.

READ = [\$604]

Reads a record from a disk file.

Entry Conditions

Register A = read option

The read options are:

Bit 0 clear — direct access (read by record number; fixed length records)

Bit 0 set — sequential access (read by terminator character; variable length records)

Bit 1 clear — exit READ pointing to next record

Bit 1 set — exit READ leaving DCBLRN and DCBRBA the same (not pointing to next record)

The other bits can contain any value.

Register U = address pointing to the DCB

Program must follow DOS programming convention

Exit Conditions:

Register A = 0 if no error; error number if error logical buffer (pointed to by DCBLRB)

contains the record

Technical Function of READ:

- Checks DCBCFS to see if the file was opened for "read."
- Checks DCBRBA for the record you want to access. (If Bit O in Register A is clear, READ calculates DCBRBA as the product of DCBLRN times DCBRSZ).
- Checks to see if the record is in the physical buffer (by comparing the high two bytes of DCBRBA with the contents of DCBPRN).
 - If the record is not in the physical buffer, READ reads the record into the physical buffer then transfers it to the logical buffer.
- Checks to see if Register A's Bit 1 is set. If so, restore DCBLRN and DCBRBA to their original values.

RELSE = [\$608]

Frees a physical buffer so that you can use it with another file.

Entry Conditions:

Register U = address where the DCB is stored of the file currently using the physical buffer.

Register A = 0 if no error; error code if error.

Technical Function of RELSE:

- Check DCBMDT. If the tag is set, the contents of the physical buffer are written to disk and DCBMDT is cleared.
- · Sets DCBPRN to \$FFFF.

WRITE = [\$606]

Writes a logical record to disk.

Entry Conditions:

Register A = read/write option

The read/write options are:

Bit 0 clear — direct access (write by record number; fixed length records)

Bit 0 set — sequential access (write by terminator character; variable length records)

Bit 1 clear — exit READ pointing to next record

Bit 1 set — exit READ leaving DCBLRN and DCBRBA the same (not pointing to next record)

The other bits can contain any value.

Register U = address pointing to the DCB logical buffer (pointed to by DCBLRB) contains the record you want to write

Program must follow DOS programming conventions.

Exit Conditions:

Register A = 0 if no error; status code if error

Technical Function of WRITE:

- · Checks DCBCFS to see if the file was opened for "write."
- Checks DCBRBA for the record you want to access. (If Bit 0 in Register A is off, WRITE calculates DCBRBA as the product of DCBLRN times DCBRSZ).
- Transfers the contents of the logical buffer to the physical buffer. If all 256 bytes of the physical buffer are full, writes the contents of the physical buffer to disk. If there is still more contents in the logical buffer, WRITE transfer these contents to the physical buffer and sets DCBMDT to 1.
- If the file mode is "share," writes the complete contents of the physical buffer to disk regardless of whether it completely fills the sector. Then, sets DCBPRN to \$FFFF.

Reference I/ DOS Error Codes

Error Code	Hex Code	Character Displayed	Error
00	40	@	No errors
01	41	Α	I/O error (drive not ready)
02	42	В	I/O error (write-protected diskette)
03	43	С	I/O error (write fault)
04	44	D	I/O error (seek error or record not found)

Reference L/ 6809 Mnemonics

Definition of Terms

Source Forms:

This shows all the possible variations you can use with the instruction. *Table 4* gives the meaning of all the notations we use. The notations in italics represent values you can supply.

For example, the BEQ instruction has two source forms. BEQ *dd* allows you to use these instructions:

BEQ \$08 BEQ \$FF BEQ \$A0

Whereas LBEQ DODD allows you these:

LBEQ \$C000 LBEQ \$FFFF

Operation:

This uses shorthand notation to show exactly what the instruction does, step by step. The meaning of all the codes are also in *Table 4*.

For example, the BEQ operation does this:

"if, (but only if), the zero flag is set, branch to the location indicated by the program counter plus the value of the 8-bit offset."

Condition Codes:

This shows which of the flags in the CC register are affected by the instruction, if any. As you'll note, BEQ does not set or clear any of the flags.

Description:

This is an overall description, in English, of what the instruction does.

Addressing Mode:

This tells you which addressing modes you may use with the instruction. BEQ allows only the Relative addressing mode.

ABBREVIATION	MEANING
ACCA or A	Accumulator A.
ACCB or B	Accumulator B.
ACCA:ACCB or D	Accumulator D.
ACCX	Either accumulator A or
	accumulator B.
CCR or CC	Condition code register.
DPR or DP	Direct page register.
EA	Effective address.
IFF	If and only if.
IX or X	Index register X.
IY or Y	Index register Y.
LSN	Least significant nibble.
M	Memory location.
MI	Memory immediate.
MSN	Most significant nibble.
PC	Program counter.
R	A register before the operation
R'	A register after the operation.
TEMP	A temporary storage location.
xxH	Most significant byte of any location.
xxL	Least significant byte of any location.
Sp or S	Hardware stack pointer.

ABBREVIATION	MEANING
Us or U	User stack pointer.
P	A memory location with immediate,
	direct, extended, and indexed
	addressing modes.
Q	A read-write-modify argument with
	direct, extended and indexed
	addressing modes.
()	The data pointed to by the enclosed
	(16 bit address).
dd	8-bit branch offset.
DDDD	16-bit offset.
#	Immediate value follows.
\$	Hexadecimal value follows.
[]	Indirection.
	Indicates indexed addressing.
←	Is transferred to.
/	Boolean AND.
V	Boolean OR.
0	Boolean Exclusive OR (XOR).
	Boolean NOT.
:	Concatination.
+	Arithmetic plus.
-	Arithmetic minus.
X	Arithmetic multiply.

Table 4. Notations and Codes

Add Accumulator B into Index Register X

Source Form: ABX Operation: IX' ←IX+ACCB Condition Codes: Not affected.

Description: Add the 8-bit unsigned value in accumulator B

into index register X.

Addressing Mode: Inherent.

Add with Carry into Register

Source Forms: ADCA P; ADCB P Operation: R'←R+M+C

Condition Codes: H — Set if a half-carry is generated; cleared otherwise.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

C — Set if a carry is generated; cleared otherwise.

Description: Adds the contents of the C (carry) bit and the memory byte into an 8-bit accumulator.

Addressing Modes: Immediate; Extended; Direct; Indexed.

Add Memory into Register

Source Forms: ADDA P; ADDB P

Operation: R'←R+M **Condition Codes:**

H — Set if a half-carry is generated; cleared otherwise.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise.

C — Set if a carry is generated; cleared otherwise.

Description: Adds the memory byte into an 8-bit

accumulator.

Addressing Modes: Immediate; Extended; Direct; Indexed.

Add Memory into Register

Source Form: ADDO P Operation: R'←R+M:M+1 **Condition Codes:**

H — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V - Set if an overflow is generated; cleared otherwise.

C - Set if a carry is generated; cleared otherwise.

Description: Adds the 16-bit memory value into the 16-bit

accumulator.

Addressing Modes: Immediate: Extended: Direct: Indexed.

Logical AND Memory into Register

Source Forms: ANDA P: ANDB P

Operation: $R' \leftarrow R \wedge M$ **Condition Codes:** H - Not affected.

N -Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V —Always cleared.

C — Not affected.

Description: Performs the logical AND operation between the contents of an accumulator and the contents of memory location M and the result is stored in the accumulator.

Addressing Modes: Immediate; Extended; Direct; Indexed.

Logical AND Immediate Memory

Source Form: ANDCC #xx Operation: $R' \leftarrow R \wedge MI$

Condition Codes: Affected according to the operation.

into Condition Code Register

Description: Performs a logical AND between the condition code register and the immediate byte specified in the instruction and places the result in the condition code

register.

Addressing Mode: Immediate.

Arithmetic Shift Left

Source Forms: ASL Q; ASLA; ASLB

Operation: C ← ←0

b7 b0

Condition Codes:

H — Undefined.

N — Set if the result is negative; cleared otherwise.

Z —Set if the result is zero; cleared otherwise.

V — Loaded with the result of the exclusive OR of bits six and seven of the original operand.

C — Loaded with bit seven of the original operand.

Description: Shifts all bits of the operand one place to the left. Bit zero is loaded with a zero. Bit seven is shifted into the C (carry) bit.

Addressing Modes: Inherent; Extended; Direct; Indexed.

ASA

Arithmetic Shift Right

Source Forms: ASR Q; ASRA; ASRB

Operation:

Condition Codes:

H — Undefined.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Not affected.

C — Loaded with bit zero of the original operand.

Description: Shifts all bits of the operand one place to the right. Bit seven is held constant. Bit zero is shifted into the

C (carry) bit.

Addressing Modes: Inherent; Extended; Direct; Indexed.

Branch on Carry Clear

Source Forms: BCC dd; LBCC DODD

Operation: TEMP←MI

IFFC=O then PC'←PC + TEMP

Condition Codes: Not affected.

Description: Tests the state of the C (carry) bit and causes a

branch if it is clear.

Addressing Mode: Relative.

Comments: Equivalent to BHS dd; LBHS DDDD.

Branch on Carry Set

Source Forms: BCS dd; LBCS DODD

Operation: TEMP←MI

IFF C = 1 then PC'-PC + TEMP

Condition Codes: Not affected.

Description: Tests the state of the C (carry) bit and causes a

branch if it is set.

Addressing Mode: Relative.

Comments: Equivalent to BLO dd; LBLO DDDD.

Branch on Equal

Source Forms: SEQ dd; LBEQ DDDD

Operation: TEMP←MI

IFF Z = 1 then PC' \leftarrow PC+ TEMP Condition Codes: Not affected.

Description: Tests the state of the Z (zero) bit and causes a branch if it is set. When used after a subtract or compare operation, this instruction will branch if the compared values, signed or unsigned, were exactly the same.

Addressing Mode: Relative.

BGE

Branch on Greater than or Equal to Zero

Source Forms: BGE dd; LBGE DDDD
Operation:

 $\mathsf{TEMP} \leftarrow \mathsf{MI}$

IFF $Z \Lambda [N \oplus V] = 0$ then $PC' \leftarrow PC + TEMP$

Condition Codes: Not affected.

Description: Causes a branch if the N (negative) bit and the V (overflow) bit are either both set or both clear. That is, branch if the sign of a valid twos complement result is, or would be, positive. When used after a subtract or compare operation on twos complement values, this instruction will branch if the register was greater than or equal to the memory operand.

Addressing Mode: Relative.

BGT

Branch on Greater

Source Forms: SGT dd; LBGT DDDD

.....

Operation: TEMP←MI

IFF $Z \Lambda [N \oplus V] = 0$ then PC'-PC + TEMP

Condition Codes: Not affected.

Description: Causes a branch if the N (negative) bit and V (overflow) bit are either both set or both clear and the

Z (zero) bit is clear. In other words, branch if the sign of a valid' twos complement result is, or would be, positive and not zero. When used after a subtract or compare operation on twos complement values, this instruction will branch if the register was greater than the memory operand.

Addressing Mode: Relative.

Branch if Higher

Source Forms: SHI dd; LBHI DDDD

Operation: TEMP←MI

IFF $[C \lor Z] = 0$ then $PC' \leftarrow PC + TEMP$

Condition Codes: Not affected.

Description: Causes a branch if the previous operation caused neither a carry nor a zero result. When used after a

subtract or compare operation on unsigned binary values, this instruction will branch if the register was higher than the memory operand.

Addressing Mode: Relative.

Comments: Generally not useful after INC/DEC. LD/TST,

and TST/CLR/COM instructions.

Branch if Higher or Same on unsigned binary values, this instruction will branch if the Source Forms: BHS dd: LBHS DDDD register was higher than or the same as the memory Operation: operand. Addressing Mode: Relative. TEMP←MI IFF C = 0 then $PC' \leftarrow PC + MI$ **Comments:** This is a duplicate assembly-language mnemonic for the single machine instruction BCC. Generally Condition Codes: Not affected. not useful after INC/DEC, LO/ST, and TST/CLR/COM **Description:** Tests the state of the C (carry) bit and causes a branch if it is clear. When used after a subtract or compare intructions. BIT V — Always cleared. **Bit Test** C — Not affected. Source Form: BIT P Description: Performs the logica! AND of the contents of BIT Operation: TEMP←R ∧ M accumulator A or B and the contents of memory location M **Condition Codes:** and modifies the condition codes accordingly. The contents H — Not affected. of accumulator A or B and memory location M are not N — Set if the result is negative; cleared otherwise. affected. Z — Set if the result is zero; cleared otherwise. Addressing Modes: Immediate; Extended; Direct; Indexed **Branch on Less than Description:** Causes a branch if the exclusive OR of the N (negative) and V (overflow) bits is 1 or if the Z (zero) bit is or Equal to Zero set. That is, branch if the sign of a valid twos complement Source Forms: BLE dd; LBLE DDDD result is, or would be, negative. When used after a subtract Operation: or compare operation on twos complement values, this TEMP←MI instruction will branch if the register was less than or equal IFF $Z v [N \oplus V] = 1$ then $PC' \leftarrow PC + TEMP$ to the memory operand. Condition Codes: Not affected. Addressing Mode: Relative. a branch if it is set. When used after a subtract or compare on **Branch on Lower** unsigned binary values, this instruction will branch if the A N Source Forms: BLO dd; LBLO DDDD register was lower than the memory operand. Operation: Addressing Mode: Relative. TEMP ← MI **Comments:** This is a dupli.cate assembly-language IFF $(C \vee Z) = 1$ then $PC' \leftarrow PC + TEMP$ mnemonic for the single machine instruction BCS. Generally not useful after INC/DEC, LO/ST, and TST/CLR/COM Condition Codes: Not affected. Description: Tests the state of the C (Carry) bit and causes instructions. caused either a carry or a zero result. When used after a **Branch on Lower or Same** subtract or compare operation on unsigned binary values, Source Forms: BLO dd: LBLO DDDD this instruction will branch ii the register was lower than or Operation: the same as the memory operand. TEMP ← MI Comments: Addressing Mode: Relative. IFF $(C \lor Z) = 1$ then $PC' \leftarrow PC + TEMP$ Comments: Generally not useful after INC/DEC, LO/ST, and Condition Codes: Not affected. TST/CLR/COM instructions. **Description:** Causes a branch if the previous operation **Branch on Less than Zero** N (negative) or V (overflow) bits is set. That is, branch if the sign of a valid twos complement result is, or would be, Source Forms: BLT dd: LBLT DDDD negative. When used after a subtract or compare operation Operation: on twos complement binary values, this instruction will TEMP ← MI branch if the register was less than the memory operand. IFF $[N \oplus V] = 1$ then PC' \leftarrow PC + TEMP Addressing Mode: Relative. Condition Codes: Not affected. Description: Causes a branch if either, but not both, of the FINT **Branch on Minus** causes a branch if set. That is, branch if the sign of the twos

Source Forms: BMI dd; LBMI DDDD

Operation: TEMP←MI

IFF N = 1 then PC' ← PC + TEMP Condition Codes: Not affected.

Description: Tests the state of the N (negative) bit and

complement result is negative.

Addressing Mode: Relative.

Comments: When used after an operation on signed binary values, this instruction will branch if the result is minus. It is generally preferred to use the LBL T instruction after signed operations.

Branch Not Equal

Source Forms: BNE dd; LBNE DDDD

Operation: TEMP ← MI

IFFZ = 0 then PC'-PC + TEMP

Condition Codes: Not affected.

Description: Tests the state of the Z (zero) bit and causes a branch if it is clear. When used after a subtract or compare operation on any binary values, this instruction will branch if the register is, or would be. not equal to the memory

operand.

Addressing Mode: Relative.

Branch on Plus

Source Forms: BPL dd: LBPL DDDD

Operation: TEMP ← MI

IFF N = 0 then PC' ← PC+ TEMP Condition Codes: Not affected.

Description: Tests the state of the N (negative) bit and

causes a branch if it is clear. That is, branch if the sign of the twos complement result is positive.

Addressing Mode: Relative.

Comments: When used after an operation on signed binary values, this instruction will branch if the result (possibly invalid) is positive. It is generally preferred to use the BGE

instruction after signed operations.

Branch Always

Source Forms: BRA dd; LBRA DDDD

Operation: TEMP ← MI PC' ← PC + TEMP Condition Codes: Not affected.

Description: Causes an unconditional branch.

Addressing Mode: Relative.

Branch Never

Source Forms: BRN dd: LBRN DDDD

Operation: TEMP ← MI Condition Codes: Not affected. **Description:** Does not cause a branch. This instruction is essentially a no operation, but has a bit pattern logically

related to branch always. Addressing Mode: Relative.

Branch to Subroutine

Source Forms: BSR dd: LBSR DDDD

Operation:

TEMP ← MI

SP' ← SP-1, CSPI ← PCL SP' ← SP- 1, CSPI ← PCH PC' ← PC + TEMP

Condition Codes: Not affected.

Description: The program counter is pushed onto the stack. The program counter is then loaded with the sum of the

program counter and the offset. Addressing Mode: Relative.

Comments: A return from subroutine CRTS> instruction is used to reverse this process and must be the last instruction

executed in a subroutine.

Branch on Overflow Clear

Source Forms: BVC dd; LBVC DDDD

Operation: TEMP ← MI

IFF V = 0 then PC' ← PC +TEMP Condition Codes: Not affected.

Description: Tests the state of the V (overflow) bit and causes a branch if it is clear. That is, branch if the twos complement result was valid. When used after an operation on twos complement binary values, this instruction will branch if there was no overflow.

Addressing Mode: Relative.

BVS Branch on Overflow set

Source Forms: BVS dd; LBVS DODD

Operation: Temp \leftarrow MI

IFF V= 1 then PC' ← PC+ TEMP Condition Codes: Not affected.

Description: Tests the state of V (overflow) bit and causes a branch if it is set. That is, branch if twos complement result was invalid. When used after an operation on twos complement binary values, this instruction will branch if there was an overflow.

Addressing Mode: Relative.

CLR Clear

Source Forms: CLR Q

Operation: TEMP \leftarrow M M \leftarrow 00 (base 16)

Condition codes: H — Not affected. N — Always cleared. Z — Always set.

V — Always cleared.

C — Always cleared.

Description: Accumulator A or B or memory location M is loaded with 00000000. Note that the EA is read during this

Addressing Modes: Inherent, Extended, Direct, Indexed.

114

Compare Memory from Register

Source Forms: CMPA P; CMPB P Operation: TEMP $\leftarrow R - M$

Condition Codes: H - Undefined.

> N - Set if the result is negative; cleared otherwise. Z - Set if the result is zero; cleared otherwise.

V — Set if an overflow is generated; cleared otherwise. C — Set if a borrow is generated; cleared otherwise.

Description: Compares the contents of memory location to the contents of the specified register and sets the appropriate condition codes. Neither memory location M nor the specified register is modified. The carry flag represents a borrow and is set to the inverse of the resulting binary carry. Addressing Modes: Immediate; Extended; Direct; Indexed.

(8-Bit)

Compare Memory from Register

Source Forms: CMPD P; CMPX P; CMPY P; CMPU P;

CMPS P

Operation: TEMP ← R - M: M + 1

Condition Codes:

H — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise. V — Set if an overflow is generated; cleared otherwise.

C — Set iF a borrow is generated; cleared otherwise. Description: Compares the 16-bit contents of the concatenated memory locations M: M + 1 to the contents of the specified register and sets the appropriate condition codes. Neither the memory locations nor the specified register is modified unless autoincrement or autodecrement are used. The carry flag represents a borrow and is set to the inverse of the resulting binary carry.

Addressing Modes: Immediate; Extended; Direct; Indexed.

CMP

(15-51-)

Complement

Source Forms: COM Q; COMA; COMB

Operation: $M' \leftarrow O + \overline{M}$ **Condition Codes:**

H — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V —Always cleared.

C —Always set.

Description: Replaces the contents of memory location M or accumulator A or B with its logical complement. When operating on unsigned values, only BEQ and BNE branches can be expected to behave properly following a COM instruction. When operating on twos complement values, all signed branches are available.

Addressing Modes: Inherent; Extended; Direct; Indexed.

Clear CC bits and Wait for Interrupt

Source Form: CWAI #\$XX

Operation: E F H I N Z V C CCR ← CCR ∧ MI (Possibly clear masks)

Set E (entire state saved)

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow PCL$ $SP' \leftarrow SP - 1$, $(SP) \leftarrow PCH$

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow USL$

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow USH$

 $SP' \leftarrow SP - 1$. $(SP) \leftarrow IYL$

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow IYH$ $SP' \leftarrow SP - 1$, $(SP) \leftarrow IXL$

 $SP' \leftarrow SP - 1. (SP) \leftarrow IXH$

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow DPR$ SP' ← SP - 1, (SP) ← ACCB

 $SP' \leftarrow SP - 1$, $(SP) \leftarrow ACCA$ $SP' \leftarrow SP - 1$, $(SP) \leftarrow CCR$

Condition Codes: Affected according to the operation.

Description: This instruction ANDs an immediate byte with the condition code register which may clear the interrupt mask bits I and F, stacks the entire machine state on the hardware stack and then looks for an interrupt. When a non-masked interrupt occurs, no further machine state information need be saved before vectoring to the interrupt handling routine. This instruction replaced the MC6800 CLI WAI sequence, but does not place the buses in a highimpedance state. A FIRQ (fast interrupt request) may enter its interrupt handler with its entire machine state saved. The RTI (return from interrupt) instruction will automatically return the entire machine state after testing the E (entire> bit of the recovered condition code register.

Addressing Mode: Immediate.

Comments: The following immediate values will have the following results:

FF= enable neither

EF =enable IRQ BF= enable FIRQ

AF= enable both

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Undefined.

C — Set if a carry is generated or if the carry bit was set before the operation; cleared otherwise.

Description: The sequence of a single-byte add instruction on accumulator A (either ADDA or ADCA) and a following decimal addition adjust instruction results in a BCD addition with an appropriate carry bit. Both values to be added must be in proper BCD form (each nibble such that: 0 ≤ nibble ≤ 9). Multiple-precision addition must add the carry generated by this decimal addition adust into the next higher digit during the add operation (ADCA) immediately prior to the next decimal addition adjust.

Addressing Mode: Inherent.

Decimal Addition Adjust

Source Form: DAA

Operation: ACCA' ← ACCA + CF (MSN):CF(LSN) where CF is a Correction Factor, as follows: the CF for each nibble <BCD> digit is determined separately, and is either 6 or 0.

Least Significant Nibble

CF(LSN) = 6 IFF 1) C = 1

or 2) LSN > 9

Most Significant Nibble

CF(MSN) = 6 IFF 1) C = 1

or 2) MSN > 9 or 3) MSN > 8 and LSN > 9

Condition Codes:

H - Not affected.

...

:	 •••••
:	 .

Decrement

Source Forms: DEC Q; DECA; DECB

Operation: M' ← M - 1 **Condition Codes:**

H — Not affected.

N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise.

V — Set if the original operand was 10000000; cleared otherwise.

C — Not affected.

Description: Subtract one from the operand. The carry bit is not affected, thus allowing this instruction to be used as a loop counter in multiple-precision computations. When operating on unsigned values, only BEQ and BNE branches can be expected to behave consistently. When operating on twos complement values, all signed branches are available. Addressing Modes: Inherent; Extended; Direct; Indexed.

EDRI

Exclusive OR

Source Forms: EORA P; EORB P

Operation: $R' \leftarrow R \oplus M$ **Condition Codes:**

H — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V —Always cleared. C — Not affected.

Description: The contents of memory location M is

exclusive ORed into an 8-bit register.

Addressing Modes: Immediate; Extended; Direct; Indexed.

Exchange Registers

Source Form: EXG R1.R2 0010 = Y1010 = CCR0011 = US1011 = DPR Operation: R1 ↔ R2 Condition Codes: Not affected Cunless one of the registers 0100 = SP1100 = Undefined 0101 = PC1101 = Undefined is the condition code registerl. Description: Exchanges data between two designated 0110 = Undefined 1110 = Undefined

registers. Bits 3-0 of the postbyte define one register, while bits 7-4 define the other, as follows:

0000 = A:B 1000 = A0001 = X1001 = B

0111 = Undefined 1111 = Undefined Only like size registers may be exchanged. CS-bit with

8-bit or 16-bit with 16-bit.I Addressing Mode: Immediate.

Increment

Source Forms: INC Q; INCA; INCB

Operation: M' ← M+1 **Condition Codes:**

H — Not affected.

N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise.

V — Set if the original operand was 01111111; cleared otherwise.

C — Not affected.

Description: Adds to the operand. The carry bit is not affected, thus allowing this instruction to be used as a loop counter in multiple-precision computations. When operating on unsigned values, only the BEQ and BNE branches can be expected to behave consistently. When operating on twos complement values, all signed branches are correctly available.

Addressing Modes: Inherent; Extended; Direct; Indexed.

Jump

Source Form: JMP EA Operation: PC' ← EA Condition Codes: Not affected. **Description:** Program control is transferred to the effective

Addressing Modes: Extended: Direct: Indexed.

Jump to Subroutine

Source Form: JSR EA

Operation:

SP' ← SP- 1, (SP)+-PCL SP' ← SP- 1, (SP)+-PCH PC' ← EA

Description: Program control is transferred to the effective address after storing the return address on the hardware stack. A RTS instruction should be the last executed

instruction of the subroutine.

Condition Codes: Not affected.

Addressing Modes: Extended; Direct; Indexed.

| Load Register from Memory

Source Forms: LOA P; LOB P

Operation: $R' \leftarrow M$ **Condition Codes:**

H — Not affected.

N — Set if the loaded data is negative; cleared otherwise.

Z — Set if the loaded data is zero; cleared otherwise.

V — Always cleared.

C — Not affected.

Description: Loads the contents of memory location M into the designated register.

Addressing Modes: Immediate; Extended; Direct; Indexed.

(S-Bit)

Load Register from Memory Source Forms: LDD P; LDX P; LDY P; LDS P; LDU P Operation: R' ← M:M + 1 Condition Codes: H — Not affected. N — Set if the loaded data is negative; cleared otherwise.	 Z — Set if the loaded data is zero; cleared otherwise. V —Always cleared. C — Not affected. Description: Load the contents of the memory location M:M + 1 into the designated 16-bit register. Addressing Modes: Immediate; Extended; Direct; Indexed. 	LD {15-Bit
Load Effective Address Source Forms: LEAX, LEAY, LEAS, LEAU Operation: R' ← EA Condition Codes: H — Not affected. N — Not affected. Z — LEAX, LEAY: Set if the result is zero; cleared otherwise. LEAS, LEAU: Not affected. V — Not affected. C — Not affected. Description: Calculates the effective address from the index	routine, and also for MC6800 INS/DES compatibility. Addressing Mode: Indexed. Comments: Due to the order in which effective addresses are calculated internally, the LEAX, X + + and LEAX,X + do not add 2 and 1 (respectively) to the X register; bu1 instead leave the X register unchanged. This also applies to the Y, U, and S registers. For the expected results, use the faster instruction LEAX 2, X and LEAX 1, X. Some examples of LEA instruction uses are given in the following table. Instruction Operation Comment	LEF
addressing mode and places the address in an indexable register. LEAX and LEAY affect the Z (zero) bit to allow use of these registers as counters and for MC6800 INX/DEX compatibility. LEAU and LEAS do not affect the Z bit to allow cleaning up the stack while returning the Z bit as a parameter to a calling	LEAX 10, X X + 10 - X Adds 5-bit constant 1 0 to X. LEAX 500, X X + 500 - X Adds 16-bit constant 500 to X. LEAY A, Y Y + A - Y Adds 8-bit accumulator to Y. LEAY D, Y Y + D - Y Adds 16-bit D accumulator to Y. LEAU -10, U U - 10 - U Subtracts 10 from U. LEAS -10, S S - 10 - S Used to reserve area on stack. LEAS 10, S S + 10 - S Used to 'clean up' stack. LEAX 5,S S + 5 - X Transfers as well as adds.	
Logical Shift Left Source Forms: LSL Q; LSLA; LSLB Operation: 0 →	 V — Loaded with the result of the exclusive OR of bits six and seven of the original operand. C — Loaded with bit seven of the original operand. Description: Shifts all bits of accumulator A or B or memory location M one place to the left. Bit zero is loaded with a zero. Bit seven of accumulator A or B or memory location M is shifted into the C Ccarryl bit. Addressing Modes: Inherent; Extended; Direct; Indexed. Comments: This is a duplicate assembly-language mnemonic for the single machine instruction ASL. 	
Logical Shift Right Source Forms: LSR Q; LSRA; LSRB Operation: 0 →	N —Always cleared. Z —Set if the result is zero; cleared otherwise. V — Not affected. C — Loaded with bit zero of the original operand. Description: Performs a logical shift right on the operand. Shifts a zero into bit seven and bit zero into the C Ccarryl bit. Addressing Modes: Inherent; Extended; Direct; Indexed.	
Multiply Source Form: MUL Operation: ACCA': ACCB' ← ACCA x ACCB Condition Codes: H — Not affected. N — Not affected. Z — Set if the result is zero; cleared otherwise. V — Not affected.	C — Set if ACCB bit 7 of result is set; cleared otherwise. Description: Multiply the unsigned binary numbers in the accumulators and place the result in both accumulators (ACCA contains the most-significant byte of the result). Unsigned multiply allows multiple-precision operations. Addressing Mode: Inherent. Comments: The C (carry) bit allows rounding the most significant byte through the sequence: MUL ADCA #0.	

				
	Negate Source Forms: NEG Q; NEGA; NEGB Operation: M' ← 0 - M Condition Codes: H — Undefined. N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise. V — Set if the original operand was 10000000.	C — Set if a borrow is generated; cleared otherwise. Description: Replaces the operand with its twos complement. The C (carry) bit represents a borrow and is set to the inverse of the resulting binary carry. Note that 80 ₁₆ is replaced by itself and only in this case is the V Coverflowl bit set. The value 00 ₁₆ is also replaced by itself, and only in this case is the C Ccarryl bit cleared. Addressing Modes: Inherent; Extended; Direct.		
HOP	No Operation Source Form: NOP Operation: Not affected.	Condition Codes: This instruction causes only the program counter to be incremented. No other registers or memory locations are affected. Addressing Mode: Inherent.		
III	Inclusive OR Memory into Register Source Forms: ORA P; ORB P Operation: R' — R v M Condition Codes: H — Not affected. N — Set if the result is negative; cleared otherwise.	 Z — Set if the result is zero; cleared otherwise. V — Always cleared. C — Not affected. Description: Performs an inclusive OR operation between the contents of accumulator A or B and the contents of memory location M and the result is stored in accumulator A or B. Addressing Modes: Immediate; Extended; Direct; Indexed. 		
OR	Inclusive OR Memory Immediate into Condition Code Register Source Form: ORCC #XX Operation: R' R v MI Condition Codes: Affected according to the operation.	Description: Performs an inclusive OR operation between the contents of the condition code registers and the immediate value, and the result is placed in the condition code register. This instruction may be used to set interrupt masks (disable interrupts) or any other bit(s). Addressing Mode: Immediate.		
	Push Registers on the Hardware Stack Source Form: PSHS register list PSHS #LABEL Postbyte: b7 b6 b5 b4 b3 b2 b1 b0 PC U Y X DP B A CC I push order → Operation: IFF b7 of postbyte set, then: SP' ← SP - 1, (SP) ← PCL SP' ← SP - 1, (SP) ← PCH IFF b6 of postbyte set. then: SP' ← SP - 1, (SP) ← USL SP' ← SP - 1, (SP) ← USH	IFF b5 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow IYL$ $SP' \leftarrow SP - 1, (SP) \leftarrow IYH$ IFF b4 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow IXL$ $SP' \leftarrow SP - 1, (SP) \leftarrow IXL$ $SP' \leftarrow SP - 1, (SP) \leftarrow IXH$ IFF b3 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow DPR$ IFF b2 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow ACCB$ IFF b1 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow ACCB$ IFF b0 of postbyte set, then: $SP' \leftarrow SP - 1, (SP) \leftarrow ACCB$ SP' \leftarrow SP - 1, (SP) \leftarrow ACCA SP' \leftarrow SP - 1, (SP) \leftarrow CCR Condition Codes: Not affected. Description: All, some, or none of the processor registers are pushed onto the hardware stack Cwith the exception of the hardware stack pointer itselfl. Addressing Mode: Immediate. Comments: A single register may be placed on the stack with the condition codes set by doing an autodecrement store onto the stack (example: STX, S).		
F'SHU	Push Registers on the User Stack Source Form: PSHU register list PSHU #LABEL Postbyte: b7 b6 b5 b4 b3 b2 b1 b0 PC U Y X DP B A CC I push order → Operation: IFF b7 of postbyte set, then: US' ← US - 1, (US) ← PCL US' ← US - 1, (US) ← PCH IFF b6 of postbyte set, then: US' ← US - 1, (US) ← SPL US' ← US - 1, (US) ← SPH	IFF b5 of postbyte set, then: US'← US - 1, (US) ← IYL US '← US - 1, (US) ← IYH IFF b4 of postbyte set, then: US '← US - 1, (US) ← IXL US '← US - 1, (US) ← IXH IFF b3 of postbyte set, then: US '← US - 1, (US) ← DPR IFF b2 of postbyte set, then: US '← US - 1, (US) ← ACCE IFF b1 of postbyte set, then: US '← US - 1, (US) ← ACCE IFF b0 of postbyte set, then: US '← US - 1, (US) ← ACCE US '← US - 1, (US) ← ACCE Condition Codes: Not affected. Description: All, some, or none of the processor registers are pushed onto the user stack (with the exception of the user stack pointer itself). Addressing Mode: Immediate. Comments: A single register may be placed on the stack with the condition codes set by doing an autodecrement store onto the stack (example: STX U)		

store onto the stack (example: STX, - - U).

Pull Registers from the Hardware Stack IFF b5 of postbyte set, then: IYH' ← (SP), SP' ← SP+ 1 Source Form: IYL' \leftarrow (SP), SP' \leftarrow SP+ 1 PULS register list IFF b6 of postbyte set, then: USH'← (SP), SP'← SP+ 1 PULS #LABEL $USL' \leftarrow (SP), SP' \leftarrow SP + 1$ Postbyte: IFF b7 of postbyte set, then: PCH' ← (SP), SP' ← SP+ 1 b7 b6 b5 b4 b3 b2 b1 b0 $PCL' \leftarrow (SP), SP' \leftarrow SP + 1$ PC U Y X DP B A CC Condition Codes: May be pulled from stack; not affected ← pull order otherwise. Operation: **Description:** All, some, or none of the processor registers IFF b0 of postbyte set, then: CCR' \leftarrow (SP), SP' \leftarrow SP+ 1 are pulled from the hardware stack (with the exception of the IFF b1 of postbyte set, then: ACCA'← (SP), SP'← SP+ 1 hardware stack pointer itself). IFF b2 of postbyte set, then: ACCB'← (SP), SP'← SP+ 1 Addressing Mode: Immediate. Operation: Description: All, some, or none of the processor registers IFF b0 of postbyte set, then: CCR' ←(US), US' + US+ 1 are pulled from the user stack Cwith the exception of the user IFF b1 of postbyte set, then: ACCA' ←(US), US' + US+ 1 stack pointer itselfl. IFF b2 of postbyte set, then: ACCB' ←(US), US' + US+ 1 Addressing Mode: Immediate. IFF b3 of postbyte set, then: DPR' \leftarrow (US), US' + US+ 1 **Comments:** A single register may be pulled from the stack IFF b4 of postbyte set, then: IXH' with condition codes set by doing an autoincrement load ←(US), US' + US+ 1 IXL' \leftarrow (US), US' + US+ 1 from the stack (example: LDX, U + +) **Rotate Left** N — Set if the result is negative; cleared otherwise. Fini . Source Forms: ROL Q: ROLA: ROLB Z — Set if the result is zero; cleared otherwise. Ç V — Loaded with the result of the exclusive OR of bits Operation: six and seven of the original operand. C — Loaded with bit seven of the original operand. b7 b0 Description: Rotates all bits of the operand one place left **Condition Codes:** through the C Ccarrvl bit. This is a 9-bit rotation. H — Not affected. Addressing Mode: Inherent; Extended; Direct; Indexed. **Rotate Right** N — Set if the result is negative; cleared otherwise. Source Forms: ROA Q; RORA; RORB Z — Set if the result is zero; cleared otherwise. V — Not affected. - C ← Operation: C — Loaded with bit zero of the previous operand. **Description:** Rotates all bits of the operand one place right through the C (carry) bit. This is a 9-bit rotation. b7 b0 **Condition Codes:** Addressing Modes: Inherent; Extended; Direct; Indexed. H — Not affected.

••••	Return from Interrupt Source Form: RTI	PCH' ←(SP), SP'← SP+ 1 PCL' ←(SP), SP'← SP+ 1
	Operation: CCR' \leftarrow (SP), SP' \leftarrow SP+ 1, then IFF CCR bit E is set, then: ACCA' \leftarrow (SP), SP' \leftarrow SP+ 1 ACCB' \leftarrow (SP), SP' \leftarrow SP+ 1 DPR' \leftarrow (SP), SP' \leftarrow SP+ 1 IXH' \leftarrow (SP), SP' \leftarrow SP+ 1 IXL' \leftarrow (SP), SP' \leftarrow SP+ 1 IYH' \leftarrow (SP), SP' \leftarrow SP+ 1 IYH' \leftarrow (SP), SP' \leftarrow SP+ 1 USH' \leftarrow (SP), SP' \leftarrow SP+ 1 USH' \leftarrow (SP), SP' \leftarrow SP+ 1 USL' \leftarrow (SP), SP' \leftarrow SP+ 1	IFF CCR bit E is clear. then: PCH ←(SP), SP'← SP+ 1 PCL' ←(SP), SP'← SP+ 1 PCL' ←(SP), SP'← SP+ 1 Condition Codes: Recovered from the stack. Description: The saved machine state is recovered from the hardware stack and control is returned to the interrupted program. If the recovered E (entire) bit is clear, it indicates that only a subset of the machine state was saved (return address and condition codes) and only that subset is recovered. Addressing Mode: Inherent.
	Return from Subroutine	Condition Codes: Not affected.
	Source Form: RTS Operation: PCH' \leftarrow (SP), SP' \leftarrow SP+ 1 PCL' \leftarrow (SP), SP' \leftarrow SP+ 1	Description: Program control is returned from the subroutine to the calling program. The return address is pulled from the stack. Addressing Mode: Inherent.
	Subtract with Borrow Source Forms: SBCA <i>P</i> ; SBCB <i>P</i> Operation: R' ← R - R- M - C Condition Codes: H — Undefined. N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise.	V — Set if an overflow is generated; cleared otherwise. C — Set if a borrow is generated; cleared otherwise. Description: Subtracts the contents of memory location M and the borrow (in the C (carry) bit) from the contents of the designated 8-bit register, and places the result in that register. The C bit represents a borrow and is set to the inverse of the resulting binary carry. Addressing Modes: Immediate; Extended; Direct; Indexed.
2000, 2000 \$. 2 000, 2000 0000 \$. 2 0000 \$. 2	Sign Extended Source Form: SEX Operation: If bit seven of ACCB is set then ACCA' ← FF ₁₆ else ACCA' ← 00 ₁₆ Condition Codes: H — Not affected.	N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero. cleared otherwise. V — Not affected. C — Not affected. Description: This instruction transforms a twos complement 8-bit value in accumulator B into a twos complement 16-bit value in the D accumulator. Addressing Mode: Inherent.
000, 00000 000, 0 000, 0	Store Register into Memory Source Forms: STA P; STB P	Z — Set if the result is zero; cleared otherwise.
(8-Bit)	Operation: N' ← R Condition Codes: H — Not affected. N — Set if the result is negative; cleared otherwise.	V — Always cleared. C — Not affected. Description: Writes the contents of an 8-bit register into a memory location. Addressing Modes: Extended; Direct; Indexed.
ST (18-Bit)	Store Register into Memory Source Forms: STD P; STX P; STY P; STS P; STU P Operation: M':M+ 1 ' ← R Condition Codes: H — Not affected. N — Set if the result is negative; cleared otherwise.	 Z — Set if the result is zero; cleared otherwise. V — Always cleared. C — Not affected. Description: Writes the contents of a 16-bit register into two consecutive memory locations. Addressing Modes: Extended; Direct; Indexed.
SUB (3-Bit)	Subtract Memory from Register Source Forms: SUSA <i>P</i> ; SUBS <i>P</i> Operation: R ← R - M Condition Codes: H — Undefined. N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise.	V — Set if the overflow is generated; cleared otherwise. C — Set if a borrow is generated; cleared otherwise. Description: Subtracts the value in memory location M from the contents of a designated 8-bit register. The C (carry) bit represents a borrow and is set to the inverse of the resulting binary carry. Addressing Modes: Immediate; Extended; Direct; Indexed.

EDTASM

Subtract Memory from Register Source Forms: SUBD P Operation: R' ← R - M:M + 1 Condition Codes H — Not affected. N — Set if the result is negative; cleared otherwise. Z — Set if the result is zero; cleared otherwise.	V — Set if the overflow is generated; cleared otherwise. C — Set if a borrow is generated; cleared otherwise. Description: Subtracts the value in memory location M: M + 1 from the contents of a designated 16-bit register. The C (carry) bit represents a borrow and is set to the inverse of the resulting binary carry. Addressing Modes: Immediate: Extended; Direct: Indexed.	SUB (16-Bi
Software Interrupt Source Form: SWI Operation: Set E (entire state will be saved) $SP' \leftarrow SP - 1, (SP) \leftarrow PCL$ $SP' \leftarrow SP - 1, (SP) \leftarrow PCH$ $SP' \leftarrow SP - 1, (SP) \leftarrow USL$ $SP' \leftarrow SP - 1, (SP) \leftarrow USH$ $SP' \leftarrow SP - 1, (SP) \leftarrow USH$ $SP' \leftarrow SP - 1, (SP) \leftarrow IYL$ $SP' \leftarrow SP - 1, (SP) \leftarrow IYH$ $SP' \leftarrow SP - 1, (SP) \leftarrow IXL$ $SP \leftarrow SP - 1, (SP) \leftarrow IXL$	SP ← SP - 1, (SP) ← DPR SP ← SP - 1, (SP) ← ACCB SP ← SP - 1, (SP) ← ACCA SP ← SP - 1, (SP) ← CCR Set I, F (mask interrupts) PC' ← (FFFA):(FFFB) Condition Codes: Not affected. Description: All of the processor registers are pushed onto the hardware stack (with the exception of the hardware stack pointer itself), and control is transferred through the software interrupt vector. Both the normal and fast interrupts are masked (disabled). Addressing Mode: Inherent.	
Software Interrupt 2 Source Form: SWI2 Operation: Set E (entire state saved) SP \leftarrow SP - 1, (SP) \leftarrow PCL SP \leftarrow SP - 1, (SP) \leftarrow PCH SP \leftarrow SP - 1, (SP) \leftarrow USL SP \leftarrow SP - 1, (SP) \leftarrow USL SP \leftarrow SP - 1, (SP) \leftarrow USH SP \leftarrow SP - 1, (SP) \leftarrow IYL SP \leftarrow SP - 1, (SP) \leftarrow IYH SP \leftarrow SP - 1, (SP) \leftarrow IXL SP \leftarrow SP - 1, (SP) \leftarrow IXL SP \leftarrow SP - 1, (SP) \leftarrow IXH	SP ←SP - 1, (SP) ← DPR SP ←SP - 1, (SP) ← ACCB SP ←SP - 1, (SP) ← ACCA SP ←SP - 1, (SP) ← CCR PC' ←(FFF4):(FFF5) Condition Codes: Not affected. Description: All of the processor registers are pushed onto the hardware stack (with the exception of the hardware stack pointer itself), and control is transferred through the software interrupt 2 vector. This interrupt is available to the end user and must not be used in packaged software. This interrupt does not mask (disable) the normal and fast interrupts. Addressing Mode: Inherent.	SWIZ
Software Interrupt 3 Source Form: SWI3 Operation: Set E (entire state will be saved) $SP \leftarrow SP - 1, (SP) \leftarrow PCL$ $SP \leftarrow SP - 1, (SP) \leftarrow PCH$ $SP \leftarrow SP - 1, (SP) \leftarrow USL$ $SP \leftarrow SP - 1, (SP) \leftarrow USH$ $SP \leftarrow SP - 1, (SP) \leftarrow USH$ $SP \leftarrow SP - 1, (SP) \leftarrow IYL$ $SP \leftarrow SP - 1, (SP) \leftarrow IYH$ $SP \leftarrow SP - 1, (SP) \leftarrow IXL$ $SP \leftarrow SP - 1, (SP) \leftarrow IXL$ $SP \leftarrow SP - 1, (SP) \leftarrow IXH$	SP ←SP - 1, (SP) ← DPR SP ←SP - 1, (SP) ← ACCB SP ←SP - 1, (SP) ← ACCA SP ←SP - 1, (SP) ← CCR PC' ← (FFF2):(FFF3) Condition Codes: Not affected. Description: All of the processor registers are pushed onto the hardware stack (with the exception of the hardware stack pointer itself), and control is transferred through the software interrupt 3 vector. This interrupt does not mask (disable) the normal and fast interrupts. Addressing Mode: Inherent	SMI3

Synchronize to External Event

Source Form: SYNC

Operation: Stop processing instructions.

Condition Codes: Not affected.

Description: When a SYNC instruction is executed, the processor enters a synchronizing state, stops processing instructions, and waits for an interrupt. When an interrupt occurs, the synchronizing state is cleared and processing continues. If the interrupt is enabled, and it last three cycles or more, the processor will perform the interrupt routine. If the interrupt is masked or is shorter than three cycles, the processor simply continues to the next instruction. While in the synchronizing state, the address and data buses are in the high-impedance state.

This instruction provides software synchronization with a hardware process. Consider the following example for highpeed acquisition of data:

FAST	SYNC Interrupt!		WAIT FOR DATA
	LDA	DISC	DATA FROM DISC AND
			CLEAR INTERRUPT
	STA	,X+	PUT IN BUFFER
	DECB		COUNT IT, DONE?
	BNF	FAST	GO AGAIN IF NOT

The synchronizing state is cleared by any interrupt. Of course, enabled interrupts at this point may destroy the data transfer and, as such, should represent only emergency conditions.

The same connection used for interrupt-driven I/O service may also be used for high-speed data transfers by setting the interrupt mask and using the SYNC instruction as the above example demonstrates.

Addressing Mode: Inherent.

Transfer Register to Register

Source Form: TFR *RI*, *R2*Operation: R1 ← R2

Condition Code: Not affected unless R2 is the condition

code reaister.

Description: Transfers data between two designated registers. Bits 7-4 of the postbyte define the source register, while bits 3-0 define the destination register, as follows:

0000 = A:B 1000 = A0001 = X 1001 = B

 0010 = Y
 1010 = CCR

 0011 = US
 1011 = DPR

 0100 = SP
 1100 = Undefined

 0101 = PC
 1101 = Undefined

 0110 = Undefined
 1110 = Undefined

 0111 = Undefined
 1111 = Undefined

Only like size registers may be transferred. (8-bit to 8-bit,

or 16-bit to 16-bit.)

Addressing Mode: Immediate.

TST

Test

Source Forms: TST Q; TSTA; TSTB

Operation: TEMP ← M - 0
Condition Codes:

H — Not affected.

N — Set if the result is negative; cleared otherwise.

Z — Set if the result is zero; cleared otherwise.

V — Always cleared.

C — Not affected.

Description: Set the N (negative) and Z (zero) bits according to the contents of memory location M, and clear the V (overflow) bit. The TST instruction provides only minimum information when testing unsigned values; since no unsigned value is less than zero, BLO and BLS have no utility. While BHI could be used alter TST, it provides exactly the same control as BNE, which is preferred. The signed branches are available.

Addressing Modes: Inherent; Extended; Direct; Indexed. **Comments:** The MC6800 processor clears the C (carry) bit.

Fast Interrupt Request (Hardware Interrupt)

Operation:

IFF F bit clear, then: $SP' \leftarrow SP-1$, $(SP) \leftarrow PCL$

SP' ← SP- 1, (SP) ← PCH Clear E (subset state is saved) SP' ← SP- 1, (SP) ← CCR Set F, I (mask further interrupts)

 $PC' \leftarrow (FFF6):(FFF7)$

Condition Codes: Not affected.

Description: A FIRQ Cfast interrupt request) with the F (fast interrupt request mask) bit clear causes this interrupt sequence to occur at the end of the current instruction. The program counter and condition code register are pushed

onto the hardware stack. Program control is transferred through the fast interrupt request vector. An RTI (return from interrupt) instruction returns the processor to the original task. It is possible to enter the fast interrupt request routine with the entire machine state saved if the fast interrupt request occurs alter a clear and wait for interrupt instruction. A normal interrupt request has lower priority than the fast interrupt request and is prevented from interrupting the fast interrupt request routine by automatic setting of the I (interrupt request mask) bit. This mask bit could then be reset during the interrupt routine if priority was not desired. The fast interrupt request allows operations on memory, TST, INC, DEC, etc. instructions without the overhead of saving the entire machine state on the stack.

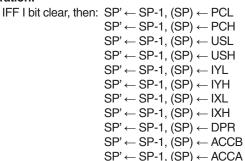

Addressing Mode: Inherent.

Interrupt Request (Hardware Interrupt)

IRQ

Operation:

Set E Centire state saved) IRQ SP' ← SP-1, (SP) ← (CCR Set I (mask further IRQ interrupts) PC' ← (FFF8):(FFF9)

Condition Codes: Not affected.

Description: If the I (interrupt request mask) bit is clear, a low level on the \overline{IRQ} input causes this interrupt sequence to occur at the end of the current instruction. Control is returned to the interrupted program using a RTI (return from interrupt) instruction. A \overline{FIRQ} fast interrupt request may interrupt a normal \overline{IRQ} (interupt request) routine and be recognized anytime after the interrupt vector is taken.

Addressing Mode: Inherent.

Non-Maskable Interrupt (Hardware Interrupt)

Operation:

```
\begin{array}{l} \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{PCL} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{PCH} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{USL} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{USH} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{IYL} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{IYL} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{IYH} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{IXL} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{IXH} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{DPR} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{ACCB} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{ACCA} \\ \mathsf{Set} \; \mathsf{E} \; (\mathsf{entire} \; \mathsf{state} \; \mathsf{save}) \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{CCR} \\ \mathsf{SP'} \leftarrow \mathsf{SP-1}, \, (\mathsf{SP}) \leftarrow \mathsf{CCR} \\ \end{array}
```

Set I, F (mask interrupts) PC' ← (FFFC):(FFFD) Condition Codes: Not affected.

Description: A negative edge on the $\overline{\text{NMI}}$ (non-maskable interrupt) input causes all of the processor's registers (except the hardware stack pointer) to be pushed onto the hardware stack. starting at the end of the current instruction. Program control is transferred through the $\overline{\text{NMI}}$ vector. Successive negative edges on the NMI input will cause successive $\overline{\text{NMI}}$ operations. Non-maskable interrupt operation can be internally blocked by a RESET operation and any non-maskable interrupt that occurs will be latched. If this happens, the non-maskable interrupt operation will occur after the first load into the stack pointer CLOS; TFR r,s; EXG r,s; etc.l after RESET.

Addressing Mode: Inherent.

Restart (Hardware Interrupt)

Operation:

 $\begin{array}{l} \text{CCR'} \leftarrow \text{X1X1XXXX} \\ \text{DPR'} \leftarrow \text{00}_{16} \\ \text{PC'} \leftarrow \text{(FFFE):(FFFF)} \end{array}$

Condition Codes: Not affected.

Description: The processor is initialized (required after power-on) to start program execution. The starting address is fetched from the restart vector.

Addressing Mode: Extended; Indirect.

Reference M/ Sample Programs

Example 1

```
10 '
         This is an example of a BASIC program that calls
20 '
         an assembly language program to paint the screen
30 '
         yellow.
40 '
60 '
         After entering the BASIC program save it on disk,
70 '
80 '
         Run DOS and enter the assembly language program,
90 '
         Use the WO and AD assembler commands to write the
100 '
         source program to disk and to assemble it.
110 '
120 '
         After returning to BASIC, load the assembled
130 '
         program into memory with the LOADM command, You
140 '
         Must load the assembled program before the BASIC
150 '
         program.
160 '
170 '
         This program demonstrates how much faster
180 '
         an assembly program can perform a function than a
190 '
         BASIC statement. After you run the program once,
200 '
         delete lines 1030, 1040, 1050, and 1120. Insert
210 '
         this statement
220 '
              1120 PAINT (1,1),2
230 '
         and see how much longer it takes BASIC to paint
240 '
         the entire screen yellow.
250 '
1000 'Specify the highest address BASIC can use. This
1010 '
           Prevents BASIC from using the memory that contains
